STUDIES ON THE EPOXIDATION OF METHYL MALEOPIMARATE,

TRIMETHYL MALEOPIMARATE AND TRIMETHYL FUMAROPIMARATE

Approved:

Chairman

Date approved by Chairman: 2/19/70

ACKNOWLEDGMENTS

I wish to express my sincere appreciation to Dr. Leon H. Zalkow for his inspiration during my undergraduate years of study and for his suggestion of the thesis topic and invaluable guidance and counsel during the course of my graduate work and in the preparation of this thesis.

I would also like to thank Dr. Drury S. Caine, III and Dr. Charles L. Liotta for serving as members of the reading committee.

Partial financial support of this work by the National Institute of Health is gratefully acknowledged.

Finally I wish to thank my parents, Mr. and Mrs. James Stamatakis, for their guidance, encouragement, and unselfish sacrifice in helping me pursue my education.

SUMMARY

This study was undertaken in order to clarify the uncertainties existing in the literature[1,2,3] regarding the structures and stereo-chemistry of the products formed in the reactions of various Diels-Alder adducts of levopimaric acid with peroxyacids. The epoxides 7 and 15 were unequivocally prepared and correlated with the products

obtained directly by treatment of trimethyl fumaropimarate (6) and tri-methyl maleopimarate (5) with trifluoroperacetic acid, respectively. In addition, 15 was converted into 14, and 7 was converted into 8, thus verifying these previously proposed[2,3] structures and providing evidence for the intermediacy of 7 and 15 in the formation of 8 and 14 directly from 6 and 5, respectively.

14

CHAPTER I

INTRODUCTION

This study is concerned with the reinvestigation of some of the
discrepancies in the literature[1,2,3] of the structures reported for the
epoxidation of certain Diels-Alder adducts of levopimaric acid.

The first work in this area was the investigation of the ozono-
lysis of methyl maleopimarate (1) by Wienhaus and Sandermann[4] in 1936.
These workers found that the ozonolysis of methyl maleopimarate, the
Diels-Alder adduct of levopimaric acid methyl ester and maleic anhy-
dride, gave a methyl ester, $C_{25}H_{34}O_8$ 2,[1,5] m.p. 250°. Several years
later, Ruzicka and LaLande[6] reinvestigated the reaction and found in
addition to the previous product, two other isomeric monomethyl esters
of molecular formular $C_{25}H_{34}O_6$, m.p. 226-227° and m.p. 289-290°.[7] With
the help of NMR and additional chemical evidence, Zalkow and coworkers
assigned structure 3[8,9] for the product of m.p. 226-227° and structure
4[1] for the product of m.p. 289-290°.

The structure elucidation of 4 proved to be interesting. In the
elucidation, it was observed that 4 could be prepared from 1 by treat-
ment with trifluoroperacetic acid,[10] but other peracids such as mono-
perphthatic or m-chloroperbenzoic were ineffective under the conditions
then used.[1] In this study, the reaction of 1 with m-chloroperbenzoic
acid was found to proceed very slowly. Treatment of the related

compounds, trimethyl maleopimarate (5) and trimethyl fumaropimarate (6) with trifluoroperacetic acid did not give epoxides as expected, but an "epoxide 7"[1] (actually a ketone 8)[3]* and a hydroxy lactone[1] were obtained. To establish the correct stereochemistry of these two products and a

---

*The identification of the product as an epoxide was simultaneously carried out in our laboratory and by Herz and Blackstone.[3]

strengthening of the stereochemical assignment of 4 were some of the

purposes of this research.

The treatment of trimethyl fumaropimarate (6) with trifluoro-

peracetic acid was reported[1] to yield epoxide 7. According to work in

our laboratory and by Herz, *et al.*,[3] the presumed "epoxide 7" showed

properties of a ketone (weak positive Cotton effect in the ORD

curve) and therefore based on this and other evidence (presented below)

the structure 8 was proposed. Herz reasoned that the misidentification

of 8 as an epoxide was due to the NMR signal at δ 3.13 which was

assigned to the proton at C-14, but which was actually due to the proton

at C-15 or C-16. The above conclusion was suggested after comparison of

9   10

the NMR spectrum of compound 9, with that of its dihydro derivative

10.[3] In the NMR spectrum of 9, the signal at δ 3.30 was assigned to

the allylic proton at C-12, while in compound 10 a two proton signal

at δ 3.10 was assigned to protons at C-15 and C-16, and a one proton

signal at δ 2.70 was assigned to the C-12 proton.[3]

The reaction of trimethyl fumaropimarate (6) with m-chloro-

perbenzoic acid was slow, but a product in harmony (IR and NMR) to the

previously postulated structure 7 was obtained.[*] The most convincing

evidence for structure 7, came from the observation that epoxide 4[1,2]

could be converted into epoxide 7 and treatment of epoxide 7 with tri-

fluoroacetic acid resulted in the formation of ketone 8.[**] With

trifluoroperacetic acid the first step proposed[3] is the formation of

---

[*]Epoxide 7 was prepared independently in our laboratory and by
Herz and Blackstone.[3]

[**]This reaction was observed independently in our laboratory and
by Herz and Blackstone.[3]

5

the epoxide 7 which in the presence of the Lewis acid, trifluoroacetic acid, rearranges by a pinacol rearrangement to the ketone 8. The preference of a pinacol rearrangement over rearside attack by an external nucleophile was believed due to the severe hindrance for the displacement of the epoxide function once it has coordinated with the acidic reagent. The stereochemistry of ketone 8 at C-13 was suggested by the inversion at C-13 due to the intramolecular rearside attack by the hydride ion, an arrangement which from inspection of the models should be favored thermodynamically.

Treatment of 5 with trifluoroperacetic acid in methylene chloride did not give either an epoxide or a ketone, but rather a hydroxy lactone.[1] The suggested structure 11[1] was postulated to have arisen *via* the intermediate epoxide 12 which in the presence of tri-fluoroacetic acid undergoes rearside attack by the β-oriented C-15 carbomethoxy nucleophile.

11   12

The apparent stereospecificity observed in the epoxidation of 5
and 6 was explained[1] in the following manner. Looking at a model of 6,
the face of the double bond *anti* to the angular C-10 methyl group
appeared less hindered than the *syn* side. In 5, however, the *syn* face
appeared less hindered. To explain the epoxidation of 1 from the *anti*
face, it was postulated that the anhydride ring was converted by tri-
fluoroperacetic acid or ozone in acetic acid, into an intermediate
peroxide, such as 13, which then reacted by an intramolecular rearrange-
ment to give 4.

13

However, recent work carried out on bicyclic systems by Zalkow
and Gabriel,[11] indicate that steric factors, rather than anhydride
participation, first postulated by Henbest[12] are involved in epoxida-
tions of bicyclic anhydrides.

Langlois and Gastambide,[2] in 1965, investigated a product
obtained both by the action of methanol-sulfuric acid upon 4 and by
the action of p-nitroperbenzoic acid upon 5, that had similar properties

to the hydroxy lactone reported by Zalkow, *et al.,*[1] but their work did

not support the previously assigned structure. These workers maintained

that the hydroxyl group was both *endo* and secondary and proposed struc-

ture $\underline{14}$[2] for this product. The hydroxyl group was assigned the *endo*

$\underline{14}$

configuration on the basis of an infrared band at 3460 cm^{-1} which indi-

cated intramolecular hydrogen bonding and secondary and hindered by the

observation that the hydroxyl function could not be oxidized in good

yield except under strenuous conditions.

Langlois and Gastambide[2] rationalized that $\underline{14}$ arose *via* the

intermediate $\underline{15}$, which undergoes an unusual *cis* opening of the epoxide

ring, rather than the classical[13,14] backside opening to give trans

diaxial products.

Evidence obtained in our laboratory supports the rationalization

of Langlois and Gastambide[2] for the formation of hydroxy lactone $\underline{14}$.

It was found that epoxide $\underline{15}$, obtained by the treatment of $\underline{5}$ with

m-chloroperbenzoic acid, on treatment with trifluoroacetic acid gave a

hydroxy lactone identical to the hydroxy lactone prepared by the

15

procedure of Zalkow *et al.*,[1] and by the procedure of Langois *et al.*,[2] involving conversion of 4 into 14 by treatment with methanolic sulfuric acid.

CHAPTER II

INSTRUMENTATION AND EQUIPMENT

Melting points were determined using a Thomas-Hoover capillary melting point apparatus and are uncorrected. Elemental microanalyses were performed by Alfred Bernhardt Microanalytical Laboratories, Mulheim, West Germany.

Infrared spectra were recorded using a Perkin-Elmer 237B spectrophotometer. The infrared spectra of liquids were taken as a thin film between two sodium chloride plates, and with solids in the form of potassium bromide pellets. The band at 1601 cm^{-1} of a polystyrene film (0.05 mm) was used as a reference point.

Nuclear magnetic resonance (NMR) spectra were obtained using a Varian Associates Model A-60 spectrometer (60 Mc spectra), or a JEOL Company Model 4H-100 spectrometer (100 Mc spectra[*]). Chemical shifts are reported in ppm downfield from the internal standard, tetramethylsilane.

Mass spectral data were obtained using a Varian Associates Model M-66 mass spectrometer.[*]

The optical rotary dispersion and circular dichroism spectra were obtained with a Jasco Model ORD/UV-5 spectrophotometer.[**]

Gas-liquid chromatography (GLC) was performed using a F&M Model 400 Biomedical gas chromatograph with a glass column and a hydrogen

---

[*]These spectra were run by Mr. George Turner.

[**]These spectra were run by Mr. Kenneth French.

flame detector. All GLC analyses were performed on a glass column
(6 ft. x 1/8 in. inside diameter) bent in a U shape and packed with
10 per cent SE-30 on 100-120 mesh Gas-Chrom Q unless otherwise stated.
The relative peak areas were measured using a Gelman Instruments
Company planimeter or by accurately cutting out the peaks and weighing
them on an analytical balance. The column substrates and solid supports
used in the GLC analyses were obtained from Applied Science Laboratories
or from Hewlett Packard Analytical Instruments. GLC analyses were per-
formed on all products of reactions and for the compounds being compared
a mixed injection was also carried out.

CHAPTER III

EXPERIMENTAL

Preparation of Epoxide 4

Procedure I--Reaction of Methyl Maleopimarate (1) with
Trifluoroperacetic Acid[1],[10]

Methyl maleopimarate[8] (1) (2.5g) was dissolved in methylene

chloride (30 ml), containing a suspension of anhydrous disodium hydro-

gen phosphate (4 g). To this was added with stirring a solution of

trifluoroperacetic acid over an interval of 20 minutes. The trifluoro-

peracetic acid was prepared by the dropwise addition at 0°C of 90 per

cent hydrogen peroxide (1 ml) to a suspension of trifluoroacetic anhy-

dride (3 ml) in 10 ml of methylene chloride.[10] After the addition was

complete, the solution was refluxed for 45 minutes and then stirred an

additional 48 hours at room temperature. The solution was washed with

10 per cent aqueous sodium sulfite (100 ml), followed by 10 per cent

aqueous sodium bicarbonate (150 ml) and then the solution was filtered

(very little material remained on the filter paper and this was dis-

carded). The organic filtrate was washed with water (200 ml), dried

over anhydrous magnesium sulfate, and concentrated with a rotary

evaporator to yield 2.2 g of crude crystalline product. Fast recrystal-

lization of the product from hot acetone gave 4 as well formed rhombic

shaped crystals, m.p. 291-294°C (lit.[1] m.p. 289-290°C); v_{max}^{KBr} 2950,

1775 and 1720 cm^{-1}. The NMR spectrum (60 Mc Instrument, $CDCl_3$) showed

signals δ 0.71 (3H, d, isopropyl, J=7 cps), 0.83 (3H, s, C-10 methyl

group, 1.05 (3H, d, isopropyl, J=7 cps), 1.17 (3H, s, C-4 methyl group),

3.20 (1H, s, H-14) and 3.67 (3H, s, ester, O-$\underline{CH}_3$). Using a 100 Mc

instrument the following signals were observed: δ 0.70 (d, isopropyl,

J=7 cps) 0.83 (s, C-10 methyl group), 1.02 (d, isopropyl, J=7 cps),

1.18 (s, C-4 methyl group), 3.19 (s, H-14) and 3.66 (s, ester, O-$\underline{CH}_3$).

This material was identical (GLC,[*] IR, and NMR) to a sample prepared

by Kulkarni and Girotra.[**]

Procedure II--Reaction of Methyl Maleopimarate (1) with m-Chloroperbenzoic Acid

m-Chloroperbenzoic acid (0.721 g, 85%, Aldrich Company) was added

to a stirred solution of methyl maleopimarate (1) (1.5 g) in methylene

chloride (30 ml). GLC analysis (C.T. 250°C, H.F.R. 67 ml/min.)[***] five

days after the reaction was started, showed the presence of starting

material, R_t 4.2 min (65%) and one compound with R_t 8.8 min (35%) which

was identical by mixed injections with epoxide 4 prepared from methyl

maleopimarate and trifluoroperacetic acid (Procedure I). Since the

reaction was progressing slowly, 15 days after the reaction was started

additional m-chloroperbenzoic acid (0.480 g) was added. After 17 days,

---

[*] As stated in the Instrumentation and Equipment Section, all GLC analyses were done on the compounds alone and by mixed injections with the compound being compared.

[**] The author is grateful to M. V. Kulkarni and N. N. Girotra for a sample of compound 4.

[***] Unless otherwise stated, all GLC analyses as explained in the Instrumentation and Equipment section are performed on a glass column packed with 10 per cent SE-30 on 100-120 mesh Gas Chrom Q.

a GLC analysis (3% OV-1 on 100/120 mesh GCQ column, C.T. 260°C, H.F.R. 73 ml/min) showed five components. Mixed injections showed that the compound with R_t 4.2 min (5.4%) was starting material, methyl maleopimarate and the major component with R_t 9.2 min (69%) was epoxide 4. Approximately three-fourths (3/4) of the solution was removed and filtered. The filtrate was washed with 10 per cent aqueous sodium sulfite (70 ml), followed by 10 per cent aqueous sodium bicarbonate (100 ml) and finally with cold water (120 ml). The methylene chloride was dried over anhydrous magnesium sulfate and concentrated with a rotary evaporator to yield 0.78 g of semicrystalline material. Slow recrystallization from hot acetone gave pure compound 4 as well formed rhombic shaped crystals, m.p. 273-279°C. The product was identical by IR and in mixed injections on the GLC to product 4 prepared by Procedure I.

The solution that was not worked up at first was later worked up in the same manner as was described above and an additional 0.142 g of product was obtained.

Preparation of Epoxide 7

Procedure I--Reaction of Trimethyl Fumaropimarate (6) with m-Chloroperbenzoic Acid

m-Chloroperbenzoic acid (0.644 g, 85%, Aldrich Company) was added to a stirred solution of trimethyl fumaropimarate (6) (1.5 g) in methylene chloride (30 ml). Additional m-chloroperbenzoic acid (0.644 g) was added 24 hours after the reaction was started. The reaction was followed by GLC and after 24 days, stirring at room temperature, a GLC

analysis (C.T. 255°C, H.F.R. 80 ml/min) showed one peak, R_t 5.2 min

(100%). During this period of time a large amount of the solvent had

evaporated and this gave rise to a large precipitate of m-chlorobenzoic

acid. The solution was filtered to remove the precipitated m-chloro-

benzoic acid and the resulting filtrate was washed with 10 per cent

aqueous sodium sulfite (80 ml). The solution was filtered again (nothing

was removed) and the filtrate was further washed with 10 per cent aqueous

sodium bicarbonate (100 ml) and water (70 ml). The methylene chloride.

was dried over anhydrous magnesium sulfate and concentrated to dryness

to yield 1.36 g of a clear oily product. A number of different solvents

were tried, but the product could not be crystallized from them.

However, crystals were obtained by the following procedure: the product

was dissolved in hot hexane and the solution was allowed to stand until

a turbid solution was obtained. The turbid solution was filtered slowly

and the filtrate was allowed to stand for several days allowing a slow

evaporation of solvent. Compound 8, identical (IR and NMR) with the

non-crystalline material, was obtained as a crystalline solid, m.p.

130.5-132.5°C;[*] ν_{max}^{KBr} 2950, 1750, 1738 and 1727 cm^{-1}. The NMR spectrum

(60 Mc, CDCl$_3$) showed signals at δ 0.77 (3H, d, isopropyl, J=6.5 cps),

0.82 (3H, s, C-10 methyl group), 1.10 (3H, d, isopropyl, J=6.5 cps),

1.17 (3H, s, C-4 methyl group) 3.13 (1H, s, H-14), 3.64 (3H,

s, ester, O-CH$_3$), 3.67 (3H, s, ester, O-CH$_3$), 3.74 (3H, s, ester,

---

[*] Epoxide 7 was prepared independently in our laboratory and by Herz and Blackstone.[3] The material reported by the latter workers was noncrystalline, and therefore a comparison of melting points was not possible.

O-$\underline{CH}_3$); 100 Mc: δ 0.77 (d, isopropyl, J=6.0 cps), 0.79 (s, C-10 methyl

group), 1.08 (3H, d, isopropyl, J=6.0 cps), 1.16 (s, C-4 methyl group),

3.13 (s, H-14), 3.60 (s, ester, O-$\underline{CH}_3$), 3.70 (s, ester, O-$\underline{CH}_3$), 3.73

(s, ester, O-$\underline{CH}_3$). The compound did not show a Cotton effect in its

CD and ORD curves.

Anal. Calcd. for $C_{27}H_{40}O_7$: C, 68.12; H, 8.47

Found: C, 67.96; H, 8.28.

Procedure II--Treatment of Anhydride Epoxide 4 with Sodium Hydroxide and Methanol

The anhydride epoxide 4 (440 mg) was added to a stirred solution

of 25 per cent aqueous sodium hydroxide (12.5 ml) in methanol (12.5 ml).

After the solution had been refluxed on a steam bath for 48 hours, it

was diluted with water (100 ml) and filtered. The filtrate was acidi-

fied with dilute hydrochloric acid until a pH of 2 was obtained (pH

paper) and extracted with ether. The organic layer, after drying with

magnesium sulfate, was evaporated to give 315 mg of a clear glassy

material. This material (315 mg) was dissolved in ether and to this

solution, diazomethane in ether was added until a yellow color persisted.

The excess diazomethane and ether were allowed to evaporate very slowly

during which time a semicrystalline material was formed which could not

be recrystallized from ether. Recrystallization from hexane, by the

method described in the preparation of 7 with m-chloroperbenzoic acid

(Procedure I above), gave 100 mg of pure compound 7 as a crystalline

solid, m.p. 134-136°C. The material was identical in melting point,

IR and NMR spectra with epoxide 7 obtained by the action of m-chloro-

perbenzoic acid on trimethyl fumaropimarate.

Preparation of Ketone 8

Procedure I--Reaction of Trimethyl Fumaropimarate (6)
with Trifluoroperacetic Acid[1]

Trimethyl fumaropimarate (6)[9] (1.08 g) was dissolved in methylene

chloride (30 ml), containing a suspension of anhydrous disodium hydrogen

phosphate (4 g). To this was added with stirring a solution of tri-

fluoroperacetic acid* over an interval of 20 minutes. After the addi-

tion was complete, the solution was refluxed for 45 minutes and then

stirred at room temperature an additional 48 hours. The solution was

washed with 10 per cent aqueous sodium sulfite (100 ml) and then fil-

tered (nothing was removed by the filtration). The filtrate was

further washed with 10 per cent aqueous sodium bicarbonate (200 ml) and

finally with water. The organic layer was dried over anhydrous magne-

sium sulfate and concentrated to yield a colorless glassy solid (0.67

g). This solid on recrystallization from ether gave 8 as a crystalline

product, m.p. 183-184°C (lit. m.p.[1] 179-181°C); ν_{max}^{KBr} 2945, 1728, and

1705 cm^{-1}. The NMR spectrum (60 Mc, $CDCl_3$) showed signals at δ 0.72

(3H, s, C-10 methyl group), 0.99 (3H, d, isopropyl, J=6 cps), 1.11

(3H, s, C-4 methyl group), 1.31 (3H, d, isopropyl, J=6 cps), 3.62 (3H,

s, ester, O-CH$_3$), 3.66 (3H, s, ester, O-CH$_3$), 3.75 (3H, s, ester,

O-CH$_3$); 100 Mc: δ 0.70 (s, C-10 methyl group), 0.86 (d, isopropyl,

J=6 cps), 1.11 (s, C-4 methyl group), 1.30 (d, isopropyl, J=6 cps),

3.61 (s, ester, O-CH$_3$), 3.65 (s, ester, O-CH$_3$), 3.75 (s, ester, O-CH$_3$);

---

*Trifluoroperacetic acid was prepared as in Procedure I, prepa-
ration of epoxide 4.

ORD (c, 0.19745, CH_3OH): $[\Phi]_{589}$ - 120.4, $[\Phi]_{336}$ - 615, $[\Phi]_{326.5}$ -

386, $[\Phi]_{314}$ - 940, $[\Phi]_{296}$ - 1568, $[\Phi]_{280}$ - 1373, a = +11.8.

Procedure II--Reaction of Epoxide 7 with Trifluoroacetic Acid

The epoxide 7 (97.5 mg) was dissolved in methylene chloride

(10 ml) and to this stirred solution was added two drops of trifluoro-

acetic acid. The reaction was followed by GLC analysis and was shown

to yield the following percent product in the indicated time: 6 hours,

3%; 1 day 11%; 11 days 64%. GLC analysis (C.T. 250°, H.F.R. 92 ml/min)

of the reaction mixture of 11 days showed the presence of four compo-

nents with R_t 3.8, 5.2, 5.3, 7.3 min (9:64:10:17). Mixed injections

showed that the compound with R_t 5.2 min was ketone 8 and the compound

with R_t 5.3 min was starting material, epoxide 7. The organic layer

was washed with a small amount of 10 per cent aqueous sodium bicarbon-

ate, followed by water. The solution was dried over anhydrous magnesi-

um sulfate and concentrated to give 101.7 mg of semicrystalline product.

Recrystallization from ether gave 25.9 mg of compound 8 as well formed

crystals, m.p. 184.5-186°C (lit. m.p.[1] 179-181°C); v_{max}^{KBr} 2945, 1730 and

1707 cm^{-1}. This product showed no depression in a mixed melting point

determination with the material from Procedure I above.

Preparation of Hydroxy Lactone 14

Procedure I--Reaction of Trimethyl Maleopimarate (5) with Trifluoroperacetic Acid[1]

Trimethyl maleopimarate (5) (2.5 g) was dissolved in methylene

chloride (30 ml), containing a suspension of anhydrous disodium hydrogen

phosphate (4 g). To this was added with stirring a trifluoroperacetic

acid[*] solution over an interval of 20 minutes at room temperature.
After the addition was complete, the solution was refluxed for 45
minutes and then stirred an additional 48 hours at room temperature.
The solution was washed with 10 per cent sodium sulfite (220 ml),
filtered (nothing was removed by the filtration), and the filtrate
was washed with 10 per cent aqueous sodium bicarbonate (130 ml) and
finally with water (350 ml). The methylene chloride solution was
dried over anhydrous magnesium sulfate and concentrated with a rotary
evaporator to yield 2.55 g of a clear glassy product. Crystallization
from methanol gave pure compound 14 as well-formed, needle-shaped
crystals, m.p. 146-147.5°C (lit. m.p.[1] 146-148°C); ν_{max}^{KBr} 2940, 1778 and
1715 cm^{-1}. The NMR spectrum (60 Mc, $CDCl_3$) showed signals at δ 0.99
(3H, s, C-10 methyl group), 1.00 (3H, d, isopropyl, J=6.5 cps), 1.16
(3H, s, C-4 methyl group), 1.21 (3H, d, isopropyl J=6.5 cps), 3.66
(3H, s, ester, O-CH$_3$), 3.71 (3H, s, ester, O-CH$_3$), 3.96 (1H, d, H-14,
J=13 cps), (changed to a singlet, 3.98 upon addition of D_2O), 4.31
(1H, d, OH-14, J=13 cps) (disappeared on an addition of D_2O); 100 Mc:
δ 0.96 (d, isopropyl, J=6.0 cps), 0.97 (s, C-10 methyl group), 1.15
(s, C-4 methyl group), 1.19 (d, isopropyl, J=6.0 cps), 3.65 (s, ester,
O-CH$_3$), 3.70 (s, ester, O-CH$_3$), 3.95 (d, H-14, J=12.5 cps) and 4.29
(d, OH-14, J=12.5 cps).

---

[*]Trifluoroperacetic acid was prepared as in Procedure I, preparation of epoxide 4.

Procedure II--Treatment of Anhydride Epoxide 4 with Sulfuric Acid and Methanol[2]

The anhydride epoxide 4 (400 mg) was dissolved in methanol

(8 ml) and concentrated sulfuric acid (0.08 ml) was added. The solution

was refluxed in an oil bath for 17 hours. After cooling, the solution

was diluted with water (100 ml) and then extracted twice with chloro-

form (200 ml, total). The chloroform layer was washed three times with

0.25 N potassium hydroxide (100 ml, total) and finally with water (50

ml). The chloroform solution was evaporated with a rotary evaporator

to yield 0.61 mg of a light yellow liquid. Repeated recrystallizations

from methanol gave material with m.p. 119-138°C; ν_{max}^{KBr} 2940, 1775 and

1715 cm^{-1}. GLC analysis (C.T. 255°C, H.F.R. 83 ml/min) of this material

(m.p. 119-138°C) showed the presence of four components with R_t 3.7,

5.9, 7.4, 11.9 min (11:14:65:10). Mixed injections showed that the

compound with R_t 7.4 min (65%) was hydroxy lactone 14.

Procedure III--Reaction of Epoxide 15 with Trifluoroacetic Acid

Trifluoroacetic acid (5 drops) was added dropwise with stirring

to a solution of epoxide 15[*] (100 mg) in methylene chloride (10 ml). The

solution was then allowed to stir at room temperature for three days.

The organic layer was washed with a small amount of 10 per cent aqueous

sodium bicarbonate, and with cold water, then dried over anhydrous

magnesium sulfate and concentrated with a rotary evaporator to give

47.5 mg of a clear oily material, which on standing became a clear

glassy solid. GLC analysis (C.T. 255°C, H.F.R. 60 ml/min) showed the

---

[*]Preparation of this is described in the next section.

clear glassy solid to be a mixture containing three components with R_t 4.5, 6.9, 10.0 min (15:12:73). Mixed injections showed that the compound with R_t 10.0 min (73%) was hydroxy lactone 14, identical with hydroxy lactone prepared in Procedure I above. Recrystallization from methanol a number of times gave pure compound 14 as crystals, m.p. 144-146.5°C (lit. m.p.[1] 146-148°C); ν_{max}^{KBr} 2940, 1780 and 1715 cm^{-1}. The product showed no appreciable depression in a mixed melting point determination with the material from Procedure I above.

Preparation of Epoxide 15

Reaction of Trimethyl Maleopimarate (5) with m-Chloroperbenzoic Acid

First Run. Methyl maleopimarate (5) (1.5 g) was dissolved in methylene chloride (30 ml), and to this solution m-chloroperbenzoic acid (0.644 g, 85%, Aldrich Company) was added with stirring. From GLC the reaction was shown to be progressing slowly. After 11 days an additional 0.214 g of m-chloroperbenzoic acid was added and after 14 days GLC analysis indicated the presence of only 44% 15. After 19 days 57% 15 was present and an additional 0.214 g of m-chloroperbenzoic acid was added. After 25 days 62% 15 was present and again 0.214 g of per-acid was added; finally, after 44 days, GLC analysis indicated the presence of 87% 15. The organic layer was washed with 10 per cent aqueous sodium sulfite (90 ml) and then filtered (nothing was removed by the filtration). The filtrate was further washed with 10 per cent aqueous sodium bicarbonate (320 ml), then water (300 ml) and finally dried over anhydrous magnesium sulfate and concentrated with a rotary evaporator to yield a light yellow syrup (1.05 g). A GLC analysis

(C.T. 250°C, H.F.R. 87 ml/min) after work-up showed the light yellow

syrup to be a complex mixture containing five components with R_t 6.4,

7.6, 10.0, 11.0, 13.0 min (9:5:16:62:8). The major component with

R_t 11.0 min (62%) was the desired epoxide 15. As can be seen from

the GLC analysis of the product, the desired product was obtained but

a number of additional products were introduced during the work-up.

The product resisted all attempts at crystallization and because of

this a new reaction was set up in which the product would be isolated

in a different manner.

Second Run. m-Chloroperbenzoic acid (0.644 g, 85%, Aldrich

Company) was added to a stirred solution of trimethyl maleopimarate

(5) (1.5 g) in methylene chloride (30 ml). Additional m-chloroper-

benzoic acid was added one day after the reaction was started to help

speed up the reaction as had been previously done. The progress of the

reaction was followed by GLC and at the end of 28 days, stirring at

room temperature, a GLC analysis (C.T. 250°C, H.F.R. 87 ml/min) showed

the solution to be a mixture containing five components with R_t 7.5,

9.8, 10.8, 13.2, 15.0 min (6:6:83:3:3). The major component with

R_t 10.8 min was the desired epoxide 15. Evaporation of part of the

solvent and then filtration, removed a large amount of the m-chloro-

benzoic acid. With a large amount of the m-chlorobenzoic acid removed,

crystallization of the product from a number of different solvents was

tried, but with no success. An analytical sample was obtained by chroma-

tographing the mixture over silica gel (40 g) (made up in benzene) and

eluting with chloroform-benzene solvent. Concentration of the

chloroform-benzene (30:70) fraction gave epoxide <u>15</u>, as a clear

viscous substance, ν_{max}^{KBr} 2945, 1740 and 1717 cm^{-1}. The NMR spectrum

(60 Mc, CDCl$_3$) showed signals at δ 0.76 (3H, d, isopropyl, J=6.5 cps),

0.82 (3H, s, C-10 methyl group), 1.09 (3H, d, isopropyl, J=6.5 cps),

1.17 (3H, s, C-4 methyl group, 3.10 (1H, s, H-14), 3.64 (3H, s, ester,

O-C<u>H</u>$_3$), 3.65 (3H, s, ester, O-C<u>H</u>$_3$), 3.67 (3H, s, ester, O-C<u>H</u>$_3$); 100 Mc:

δ 0.72 (d, isopropyl, J=6.0 cps), 0.80 (s, C-10 methyl group), 1.07

(d, isopropyl, J=6.0cps), 1.15 (s, C-4 methyl group), 3.08 (1H, s,

H-14), 3.62 (s, ester, O-C<u>H</u>$_3$), 3.63 (s, ester, O-C<u>H</u>$_3$), 3.66 (s, ester,

O-C<u>H</u>$_3$). The mass spectrum gave a parent ion at M$^+$ = 476 (7.2%, base

peak at m/e 156) (calcd. for C$_{27}$H$_{40}$O$_7$; M$^+$ = 476). This material could

not be crystallized.

CHAPTER IV

DISCUSSION OF RESULTS

As previously stated, the goal of this work was to firmly

establish the structures and stereochemistry of the products from the

reaction of trifluoroperacetic acid with trimethyl maleopimarate (5)

and trimethyl fumaropimarate (6). Since the epoxides derived from

trimethyl maleopimarate, 15, and from trimethyl fumaropimarate, 7,

were suggested[2,3] as intermediates which could lead to the products

obtained by the action of trifluoroperacetic acid on 5 and 6, respec-

tively, it was decided to unequivocally synthesis these epoxides and

determine if in fact they could be converted into the above mentioned

products. Further, if it was possible to convert the epoxides into

the products obtained with trifluoroperacetic acid the proposed

mechanisms would be strongly supported.

Four major steps were visualized as being necessary to solve

the problem. First, preparation and characterization of authentic

samples of the products obtained from the reaction of trifluoroperacetic

acid with trimethyl maleopimarate and trimethyl fumaropimarate. Second,

preparation of the hydroxy lactone of Langlois and Gastambide[2] by the

treatment of anhydride epoxide 4 with methanolic sulfuric acid as

previously described by them and comparison of the lactone so obtained

with the one reported by Zalkow *et al.*[1] Third, the preparation and

structure elucidation of the epoxides of trimethyl maleopimarate and

trimethyl fumaropimarate. Fourth, conversion of the epoxides obtained

above in an unambiguous manner into the products obtained with tri-

fluoroperacetic acid.

Epoxidation of methyl maleopimarate (1) with trifluoroperacetic

acid[*] in methylene chloride gave 4 as rhombic shaped crystals, m.p.

291-294°C (lit.[1] m.p. 289-290°C). The infrared spectrum of 4 showed

bands at 1775 (anhydride) and 1720 (double bond) cm^{-1}. The NMR[**]

spectrum showed a singlet at δ 0.83 assigned to the C-10 methyl group,

a pair of doublets (J=7 cps) centered at δ 0.71 and δ 1.05 assigned to

the isopropyl methyl groups, and a sharp singlet at δ 3.20 assigned to

the proton at C-14.

It was previously reported[1] that no reaction of 1 was observed

with m-chloroperbenzoic acid. However, in this study the reaction was

found to occur very slowly. Thus, even in the presence of excess

m-chloroperbenzoic acid the reaction proceeded to 69 per cent completion

at room temperature only after 17 days. The epoxide obtained was

identical in all respects (m.p., IR, and GLC)[***] with the epoxide

obtained with trifluoroperacetic acid.

The treatment of trimethyl maleopimarate (5) with trifluoroper-

acetic acid in methylene chloride[1] gave a hydroxy lactone 14[2] in the

---

[*]The method of preparation of trifluoroperacetic acid is given
in the experimental section.

[**]All NMR data given are for samples run in $CDCl_3$ and on the
60 Mc NMR instrument unless otherwise stated.

[***]As stated in the Instrumentation and Equipment section, all
GLC analyses were done both on the compound alone and as a mixed injec-
tion with the compound being compared.

the form of needle shaped crystals, m.p. 146-147.5°C (lit.[1] m.p. 146-
148°C). The infrared spectrum of 14 showed bands at 3460 (intramolecular
hydrogen bonding),[2] 1778 (γ-lactone) and 1715 (ester) cm^{-1}. The NMR
spectrum showed a singlet at δ 0.99 (C-10 methyl group), a pair of
doublets (J=6.5 cps) centered at δ 1.00 and δ 1.21 (isopropyl methyl
groups), a doublet (J=13 cps) at δ 3.96 (H-14) which upon addition of
D_2O changed to a singlet, centered at δ 3.98 and a doublet at δ 4.31
(OH-14) which disappeared on addition of D_2O.

The treatment of trimethyl fumaropimarate (6) with trifluoro-
peracetic acid in methylene chloride yielded 8[3] as a crystalline
product, m.p. 183-184°C (lit.[1] m.p. 179-181°C). Product 8 showed bands
in its infrared spectrum at 1728 (ester) and 1705 (ketone) cm^{-1}. The
NMR spectrum exhibited a singlet at δ 0.72 (C-10 methyl group), and a
pair of doublets (J=6 cps) centered at δ 0.99 and δ 1.31 (isopropyl
methyl group).

With the preparation of authentic samples being complete, the
second step of comparing the hydroxy lactones was initiated. The
reaction of epoxide 4 prepared in our laboratory, with methanol-
sulfuric acid *via* the route described by Langlois and Gastambide[2] gave
a crude crystalline product containing predominantly (65%) hydroxy lac-
tone 14. The hydroxy lactone thus obtained was identical with the
product obtained from trimethyl maleopimarate and trifluoroperacetic
acid *via* the route described by Zalkow, *et al.*[1]

The reaction of trimethyl fumaropimarate with m-chloroperbenzoic
acid in methylene chloride gave initially epoxide 7 as a noncrystalline

material. Crystallization of this product from hexane by the method described in the experimental section gave crystalline 7 (m.p. 130-132.5°C)* identical in spectral (IR, NMR) properties with the non-crystalline material. It was found that the use of excess m-chloro-perbenzoic acid gave an increase in the rate of reaction with no noticeable side effects. The infrared spectrum of 7 showed the three ester absorptions at 1750, 1738, and 1727 cm^{-1}. The NMR spectrum showed a sharp singlet at δ 0.82 (C-10 methyl group) a pair of doublets (J=6.5 cps) centered at δ 0.77 and δ 1.10 (isopropyl methyl groups) and a singlet at δ 3.13 (proton at C-14). Compound 7 did not show a Cotton effect (ORD and CD) as would be expected for an epoxide. The assigned molecular formular, $C_{27}H_{40}O_7$, was further supported by com-bustion analysis.

Evidence from NMR for the presence of an epoxide ring on the C-13, C-14 bridge in these bicyclic compounds (4, 7, 15) comes from the expected upfield shift of the proton at C-14 from approximately δ 5.5 in the olefinic precursors to approximately δ 3.1,[3] the downfield shift of the angular C-10 methyl group[15,16] signal and the pronounced non-equivalence of the methyl signals of the isopropyl groups. In the Diels-Alder adducts of levopimaric acid and other compounds containing unsaturation in the C-13, C-14 bridge, the signal due to the angular C-10 methyl group is observed at δ 0.6-0.7, because of strong shielding
---

*Epoxide 7 was prepared independently by Herz and Blackstone[3] in non-crystalline form and they did not succeed in obtaining crystalline 7.

by the double bond.[15,16] In epoxides like 4,[1,2] 16[3] and 17,[3] the

angular C-10 methyl group signal is found 12-15 cycles farther

O

CO_2CH_3

CO_2CH_3

17
downfield.[3] In the NMR spectrum of all Diels-Alder adducts and com-

pounds, such as 18,[3] the signals arising from the isopropyl methyl

O

1a

4a

CO_2CH_3

18
groups appear as identical doublets or doublets of almost identical

chemical shifts near δ 1.[16,17,18,19] In epoxides like 4, 16 and 17,

the isopropyl methyl group signals appear as two non-equivalent doublets

near δ 1.05 and δ 0.7, respectively, the latter representing the methyl

group being shielded more effectively by the epoxide ring.[3]

The stereochemical assignment of the epoxide ring in 16 and 17

(and that of epoxides 4 and 7) is based on the severe steric inter-

ference, indicated in models, for approach of oxidizing agents from

the side of ring (A), and on the non-displaced chemical shift of the

angular C-10 methyl groups.[3] It was argued that if the epoxide ring was

on the alternate side, a considerable degree of shielding for the angu-

lar C-10 methyl group would be expected.[1,3] Further support for the

stereochemistry of the epoxide ring was obtained from work with the

compounds 19,[17] 20[17] and 21.[17,19] It was observed that none of these

19
20

21

compounds were attacked by ozone or by potassium permanganate, whereas

compounds like 6 under the same conditions were smoothly oxidized.[9,17]

Furthermore, treatment of 19 with m-chloroperbenzoic acid did not effect

the double bond, but resulted in a Baeyer-Villiger oxidation of the less

hindered carbonyl group.[2,17] It was suggested that the lack of reac-

tivity of 19, 20 and 21 toward oxidizing agents was due to steric

hindrance around the double bond as indicated by Dreiding models.

Introduction of a 1a-4a double bond as in 18, it was reasoned, should

restore normal accessibility. This was substantiated in the epoxida-

tion of 18, which occurred rapidly and preferentially at the bridge

double bond to give 16. Similarly the epoxidation of 22[3] with

m-chloroperbenzoic acid proceeded smoothly to give 17. From the

22

observation above, it appears that face B of the C-13, C-14 double

bond (see below) in all of the compounds discussed is severely hindered

to attack by oxidizing agents, presumably by the C-10 methyl group.

Therefore, epoxidation of 1, 5 and 6 in the presence of

m-chloroperbenzoic acid would be expected to take place from side A

(endo side) to give epoxides 4, 15 and 7, respectively.

The similarities in the NMR spectra of epoxide 4, 7 and 15

(Table 1), and in addition the similarities of these spectra with those

Table 1. Chemical Shifts of the Protons
of Epoxides 4, 7 and 15

Compound	Solvent	δ in ppm			
		C-14 Proton	C-10 Methyl	Isopropyl Methyl Groups	
4	CDCl$_3$	3.20	0.83	0.71	1.05
7	CDCl$_3$	3.13	0.81	0.77	1.10
15	CDCl$_3$	3.10	0.82	0.76	1.09

of 16 and 17 reported by Herz *et al.*,[3] strongly suggest that all of these

epoxides possess the same absolute configuration at C-13 and C-14.

Second, and most important, the epoxide 4 was converted into epoxide 7.

This conversion was carried out by refluxing epoxide 4 with NaOH-methanol for 48 hours, acidifying the reaction and then esterifying with diazomethane (scheme 1). This gave in good yield the epoxide 7, identical in all respects (m.p., IR and NMR) with an authentic sample of 7.

Scheme 1

Reaction of trimethyl maleopimarate with m-chloroperbenzoic acid in methylene chloride gave epoxide 15, as a clear viscous material which resisted all crystallization attempts. Since the reaction was slow, again it was found useful to use excess m-chloroperbenzoic acid (see experimental section). The infrared absorption for the three ester groups (1740-1717 cm^{-1}) could not be resolved.* The NMR spectrum of 15 shows a sharp singlet at δ 0.82 (C-10 methyl group), a pair of doublets (J=6.5 cps) centered at δ 0.76 and δ 1.09 (isopropyl methyl groups) and a singlet at δ 3.10 for the proton at C-14. The mass
*The infrared was taken on the clear viscous material.

spectrum gave the parent ion at M^+ = 476 (calcd. for $C_{27}H_{40}O_7$; M^+ = 476).

It is interesting to note that 4 could not be converted into 15 with methanolic-diazomethane (no reaction occurred), conditions which suffice for the conversion of 1 into 5.[1] The lack of reactivity of the anhydride moiety in 4 with methanolic diazomethane may arise from the decreased electrophilicity of the anhydride carbonyl groups in 4 as a result of electron donation from the *syn* epoxide oxygen.
The assignment of structure 15 to the product obtained as described above was based on NMR data and on the important conversion of 15 to the hydroxy lactone 14. Thus the expected upfield shift of the proton at C-14, the downfield shift of the C-10 methyl group, the pronounced non-equivalence of the signals of the methyls of the iso-propyl group all are indicative of an *endo* epoxide ring in 15. The conversion of epoxide 15 into the hydroxy lactone 14 (scheme 2), by treatment of 15 with a trace of trifluoroacetic acid, further substanti-ated the stereochemistry of the epoxide ring. It was shown earlier that the hydroxy lactone 14 could be prepared from epoxide 4,[1,2] by using methanol-sulfuric acid as the reagent.[2] Since both 4 and 15 gave the same hydroxy lactone 14, in unambiguous one step reactions, it can only mean that the stereochemistry of the epoxide ring in both epoxides is the same.
Scheme 2

Treatment of epoxide 7 at room temperature with a trace of trifluoroacetic acid resulted in the formation of a ketone, identical in all respects (m.p., IR and GLC) to the ketone 8 obtained by the action of trifluoroperacetic acid on 6 as discussed earlier (scheme 3). The proposed mechanism for the formation of ketone 8 is given in the introduction. In the proposed mechanism, epoxide 7 is considered the intermediate (supported by the above reaction), which in the presence of acid, rearranges by a pinacol rearrangement to the ketone 8.[3] The structure and stereochemistry of ketone 8 follows from its method of preparation from epoxide 7, the stereochemistry of the epoxide ring in the latter having been established as discussed above.
Scheme 3

8

7

6

CF₃CO₂H

CF₃CO₃H

Further support for the stereochemistry of ketone 8 comes from a comparison with the reported NMR spectra of 23 and 24.[3] The assigned

23

24

stereochemistry of the isopropyl groups in 23 and 24 is based on the

NMR signals for the isopropyl methyl groups. According to Herz,[3]

> . . . the NMR spectra of precursors 16 and 17 show that the
> methyl doublet at lower field (at 1.07 and 1.04 ppm) has not
> been affected significantly by the pinacol rearrangement,
> whereas the more shielded methyl doublet, formerly at 0.80
> and 0.76 ppm, has experienced a further upfield shift to
> 0.67 and 0.63 ppm, respectively. This is consistent with
> that orientation, that is, 23 and 24, in which one of the
> methyl groups experiences greater shielding by the conjugated
> double bond and perhaps the carbonyl and which, from inspec-
> tion of the models, should interpose a very considerable
> amount of steric hindrance to the potential reactions of the
> carbonyl group.[3]

This was actually found to be the case. "24 and 8[1] were not only

unreactive toward the usual carbonyl reagents and toward sodium boro-

hydride, but did not undergo the Baeyer-Villiger oxidation."[3] Accord-

ing to Herz, the stereochemical assignment for the isopropyl group is

particularly clear in the conversion of 25[3] into the ketone 26.[3] This

is based on the expected large diamagnetic shift in the methyl signals

25

26

of the isopropyl group in going from 25 to 26[3] (isopropyl methyl signals appear at δ 0.35).

The above observations on the stereochemistry of ketones 23, 24 and 26, along with the chemical evidence that the ketone 8 and 24 are unreactive toward the usual carbonyl reagents give additional proof for the stereochemistry indicated in ketone 8.

It should be noted that the *endo* epoxides are converted into ketones in the presence of Lewis acids, only in those cases in which C-16 (C-1a) is sp^2 hybridized (16, 17, 25) or the substitutent at C-16 is α oriented (7). That is, in those cases in which the resulting *exo* isopropyl group is sterically unhindered. By contrast, when the epoxide contains a β oriented substituent at C-16 (15), it rearranges in the presence of a Lewis acid to give a lactone containing an *endo* isopropyl group (14) by an unusual front side opening of the epoxide ring.

The conversion of epoxide 15 into the hydroxy lactone 14 was accomplished as reported earlier by the addition of a trace amount of trifluoroacetic acid to the epoxide 15. The hydroxy lactone obtained was identical in all respects (m.p., IR, and mixed injections on GLC) to an authentic sample prepared from trimethyl maleopimarate by trifluoroperacetic acid and from epoxide 4 by methanol-sulfuric acid.
Langlois and Gastambide, as previously reported,[2] assigned the *endo* configuration to the hydroxyl group in the hydroxy lactone 14 on the basis of the infrared band at 3460 cm^{-1} (intramolecular hydrogen bonding), and they assumed the hydroxyl group was secondary and hindered on the basis of chemical evidence. Further, as was reported

earlier, these workers observed that 14 could be prepared from epoxide 4.

Based on the above observations, these workers assigned structure 14, to the hydroxy lactone prepared from trimethyl maleopimarate with peracids, and postulated that the hydroxy lactone 14 arose *via* the intermediate 15, by an unusual cis opening of the epoxide ring, rather than the classical backside opening observed up to that time. (In 1968, another observation of cis opening of an epoxide was reported.[20])

The transformation of epoxide 15 as noted above, in one step into the hydroxy lactone 14 supports the rationalization of *cis* epoxide opening and the mechanism for the formation of the hydroxy lactone 14 (scheme 4).

Scheme 4

CHAPTER V

CONCLUSIONS

Epoxides 7 and 15 prepared from trimethyl fumaropimarate and trimethyl maleopimarate, respectively, have been prepared and their structures elucidated. These epoxides 7 and 15 have been transformed in an unambiguous manner into compounds 8 and 14, respectively, and these conversions provide further verification for structures 8 and 14. Further, these transformations provided evidence that epoxides 7 and 15 were indeed intermediates in the direct formation of 8 and 14 from trimethyl fumaropimarate (6) and trimethyl maleopimarate (5), respectively, by treatment with trifluoroperacetic acid. Lastly, epoxides 4, 7 and 15 were shown to have the same stereochemistry for their epoxide rings, by chemical interconversion and comparison of their NMR spectra.

CHAPTER VI

RECOMMENDATIONS

The structure analysis by X-ray of any one of the epoxides, 4, 7 or 15, would provide exact information regarding the steric environment around the C-13, C-14 bond. This work has provided chemical and NMR evidence which is suggestive of this steric environment.

APPENDIX

The reported quantities for the ORD measurements[21] were calculated as shown in Equations 1-4, where α_{314} is the rotation at 314 mμ, $[\alpha]_{314}$ is the specific rotation at 314, and $[\Phi]_{314}$ is the molecular rotation at 314 mμ.

$$\alpha_{314} = (\text{instrument scale in degrees}) \times (\text{chart measurement}) \quad (1)$$

$$[\alpha]_{314} = \frac{100 \times \alpha_{314}}{(\text{Conc. in gm/100 ml}) \times \left(\begin{array}{c}\text{Path length of transmitted} \\ \text{light in dm}\end{array}\right)} \quad (2)$$

$$[\Phi]_{314} = \frac{[\alpha]_{314} \times (\text{mol. wt.})}{100} \quad (3)$$

$$a = \frac{[\Phi]_1 - [\Phi]_2}{100} \quad (4)$$

The molecular amplitude, a, is defined as the difference between the molecular rotation at the extremum (peak or trough) of the longer wavelength $[\Phi]_1$, and the molecular rotation at the extremum of shorter wavelength $[\Phi]_2$, divided by 100.
