**INSTITUTE OF PAPER SCIENCE AND TECHNOLOGY
PURPOSE AND MISSION STATEMENT**

The Institute of Paper Science and Technology is a unique organization whose charitable, educational, and scientific purpose evolves from the singular relationship between the Institute and the pulp and paper industry which has existed since 1929. The purpose of the Institute is fulfilled through three missions, which are:

- to provide high quality students with a multidisciplinary graduate educational experience which is of the highest standard of excellence recognized by the national academic community and which enables them to perform to their maximum potential in a society with a technological base; and
- to sustain an international position of leadership in dynamic scientific research which is participated in by both students and faculty and which is focused on areas of significance to the pulp and paper industry; and
- to contribute to the economic and technical well-being of the nation through innovative educational, informational, and technical services.

ACCREDITATION

The Institute of Paper Science and Technology is accredited by the Commission on Colleges of the Southern Association of Colleges and Schools to award the Master of Science and Doctor of Philosophy degrees.

NOTICE AND DISCLAIMER

The Institute of Paper Science and Technology (IPST) has provided a high standard of professional service and has put forth its best efforts within the time and funds available for this project. The information and conclusions are advisory and are intended only for internal use by any company who may receive this report. Each company must decide for itself the best approach to solving any problems it may have and how, or whether, this reported information should be considered in its approach.

IPST does not recommend particular products, procedures, materials, or service. These are included only in the interest of completeness within a laboratory context and budgetary constraint. Actual products, procedures, materials, and services used may differ and are peculiar to the operations of each company.

In no event shall IPST or its employees and agents have any obligation or liability for damages including, but not limited to, consequential damages arising out of or in connection with any company's use of or inability to use the reported information. IPST provides no warranty or guaranty of results.

The Institute of Paper Science and Technology assures equal opportunity to all qualified persons without regard to race, color, religion, sex, national origin, age, handicap, marital status, or Vietnam era veterans status in the admission to, participation in, treatment of, or employment in the programs and activities which the Institute operates.

EXECUTIVE SUMMARY

Strength requirements for Shipping Bag Kraft Paper are given in Rule 40 of Uniform Freight Classification 6000. Present specifications require testing with an old style tear tester, and a pendulum type tensile tester. These have largely been replaced with new style tear testers and constant rate of elongation (CRE) tensile testers.

This project was undertaken to statistically define the differences in test results that are attributable to the change in test instrumentation. For this purpose, 50 samples including 40, 50, 60, and 70 lb. flat grades and 40, 50, 60, 70 and 100 lb extensible grades were submitted by member companies of KPPD. These were Tested in the laboratories of the Institute of Paper Science and Technology. Tests included basis weight, moisture content, tear resistance and tensile properties. Tear and tensile test were made with both old style and new style testers.

Basis weight results showed that the average weight of bag paper made today is about 1.5 lbs. higher than stated grade weights. The average moisture content (air-dry basis at 50% RH) is 7.30%, with West Coast paper at about 7.4% and East Coast paper at 7.0%.

The following are conclusions based on the strength data.

Tear Resistance

1. Results obtained with new-style tear testers are 6% lower than those obtained with the old style testers.
2. Results obtained with three new-style digital instruments (Thwing Albert, L & W, and TMI) and with a new style instrument equipped with a pointer are in good agreement.

Tensile Properties

1. When testing samples having a relatively high stretch (i.e. cross machine direction of flat grades and both directions of extensible grades), the tensile strength measured with CRE type instruments averaged 2.0% lower than that measured with a pendulum type instrument.
2. When testing samples having a relatively low stretch (i.e. machine direction of flat grades), the tensile strength measured with CRE type instruments is in good agreement with that measured with a pendulum type instrument.
3. Results obtained with two CRE instruments (Instron and L & W) are in good agreement.
4. Tensile properties measured using a test span of 7.1 inches are 3% lower for tensile strength, 2.0% lower for stretch, 4% lower for TEA, and 2% higher for tensile stiffness (Et) than those measured using a

INTRODUCTION

Paper used for the construction of multi-wall paper bags must be Shipping Bag Kraft paper, and must meet certain requirements of basis weight, tear resistance, and tensile properties. The strength level requirements and testing procedures are specified in Rule 40, Section 10, of Uniform Freight Classification 6000.

The present rule specifies the use of constant rate of loading (pendulum type) testers for the measurement of tensile strength; and an old-style tear tester (without the cutout which prevents specimens from rubbing against the sector during the test) for measuring tear resistance. Most modern laboratories no longer have these instruments available.

In today's laboratories, tensile properties are usually measured on strain-gage instruments which operate at a constant rate of elongation. These instruments not only measure tensile strength, but also provide information on elongation, tensile energy absorption, and tensile stiffness (E_t). Tensile energy absorption is known to be an important performance related property of shipping bag paper.

All tear testers manufactured today have a cut out in the pendulum sector so that specimen do not rub against the sector during the test. It is well known that the test results obtained with these newer tear testers can be as much as 10% lower than those obtained with the older style, depending on the grade of paper being tested. All of the old style tear testers, and some of the new style , indicate tear resistance by means of a mechanical pointer, and clamping of the sample is accomplished with hand operated thumb screws. Many new style testers now include digital readout and pneumatic clamping.

This project was undertaken to statistically define the differences in test results that should be expected using the different methods of measurement.

SAMPLES

Member companies of KPPD were invited to submit production samples of 40, 50, 60, and 70 lb. flat grades; and 40, 50, 60, 70, and 100 lb. extensible grades. The total number of samples submitted for each grade was:

40 lb. flat	9	50 lb. flat	10
60 lb. flat	9	70 lb. flat	4
40 lb. extensible	2	50 lb. extensible	5
60 lb. extensible	5	70 lb. extensible	3
		100 lb. extensible	3

The number of samples submitted for the 40, 50, and 60 lb. grades is approximately the same as the number of participants in the KPPD baseline study (IPST Project 3710). Hence, the sample size is probably a good representation of industry production. All sample rolls, after receipt, were stored in a 20% RH environment until needed for testing.

TEST PROCEDURES

Samples for testing were preconditioned at 20% RH, 23 degrees C, for a minimum of 24 hours, and then conditioned at 50% RH, 23 degrees C for a minimum of 48 hours. All tests were conducted in the 50% RH atmosphere.

Basis weight was measured for each of the submitted samples. A few of the samples had weights significantly different than the stated grade. The results for these are tagged in this report, separate grade averages are reported including and excluding the results for the off-weight samples, and the results for these were omitted in further statistical calculations.

Moisture content (air-dry basis at 50% RH) was determined for each sample calculated from:

$$MC = 100 (w_1 - w_2) / w_1$$

where: MC = moisture content, %

w₁ = weight of specimen at 50% RH

w₂ = oven-dry weight of specimen

These data were obtained to provide an "industry average" for determining adjusted basis weight in the KPPD baseline.

The following strength tests were made. TAPPI test methods were followed except where noted. Ten replications were made for each test result.

Tensile strength using a Schopper (pendulum type) tensile tester following TAPPI method T404.

Tensile properties using an Instron (CRE type) tensile tester following TAPPI method T494.

Tensile properties using an L & W (CRE type) tensile tester following TAPPI method T494.

Tensile properties using the CRE testers and a test length of 4.8 inches rather than the 7.1 inches specified in TAPPI method T494. These tests were made for extensible grades only.

Tear resistance measured with an old-style tester, a new style tester equipped with a pointer, and digital new-style testers manufactured by Thwing-Albert (digi-tear), Testing Machines Inc. (TMI), and Lorentzen and Wettres (L & W).

TEST RESULTS

The test averages and standard deviations for each sample, and for each type of test, are given in the appendix. Each table in the appendix includes the basis weight of each sample. Test results for samples whose basis weight differed significantly from the stated grade are marked with an asterisk. Two separate grade averages were calculated for those grades including and excluding the off weight samples were used in the summary tables, graphs, and statistical calculations for the remainder of this report.

Tear Resistance

A summary of tear resistance results are given in Table 1. The results for each of the new style instruments are plotted against the results for the old style tester in Figure 1 through 4. Figure 5 is a composite graph of all test results. In each case regression coefficients were calculated so that the regression line passed through the origin. These coefficients, along with R squared values are given in the upper left of each graph. The standard error of the Y estimate for each graph are tabulated in Table 7.

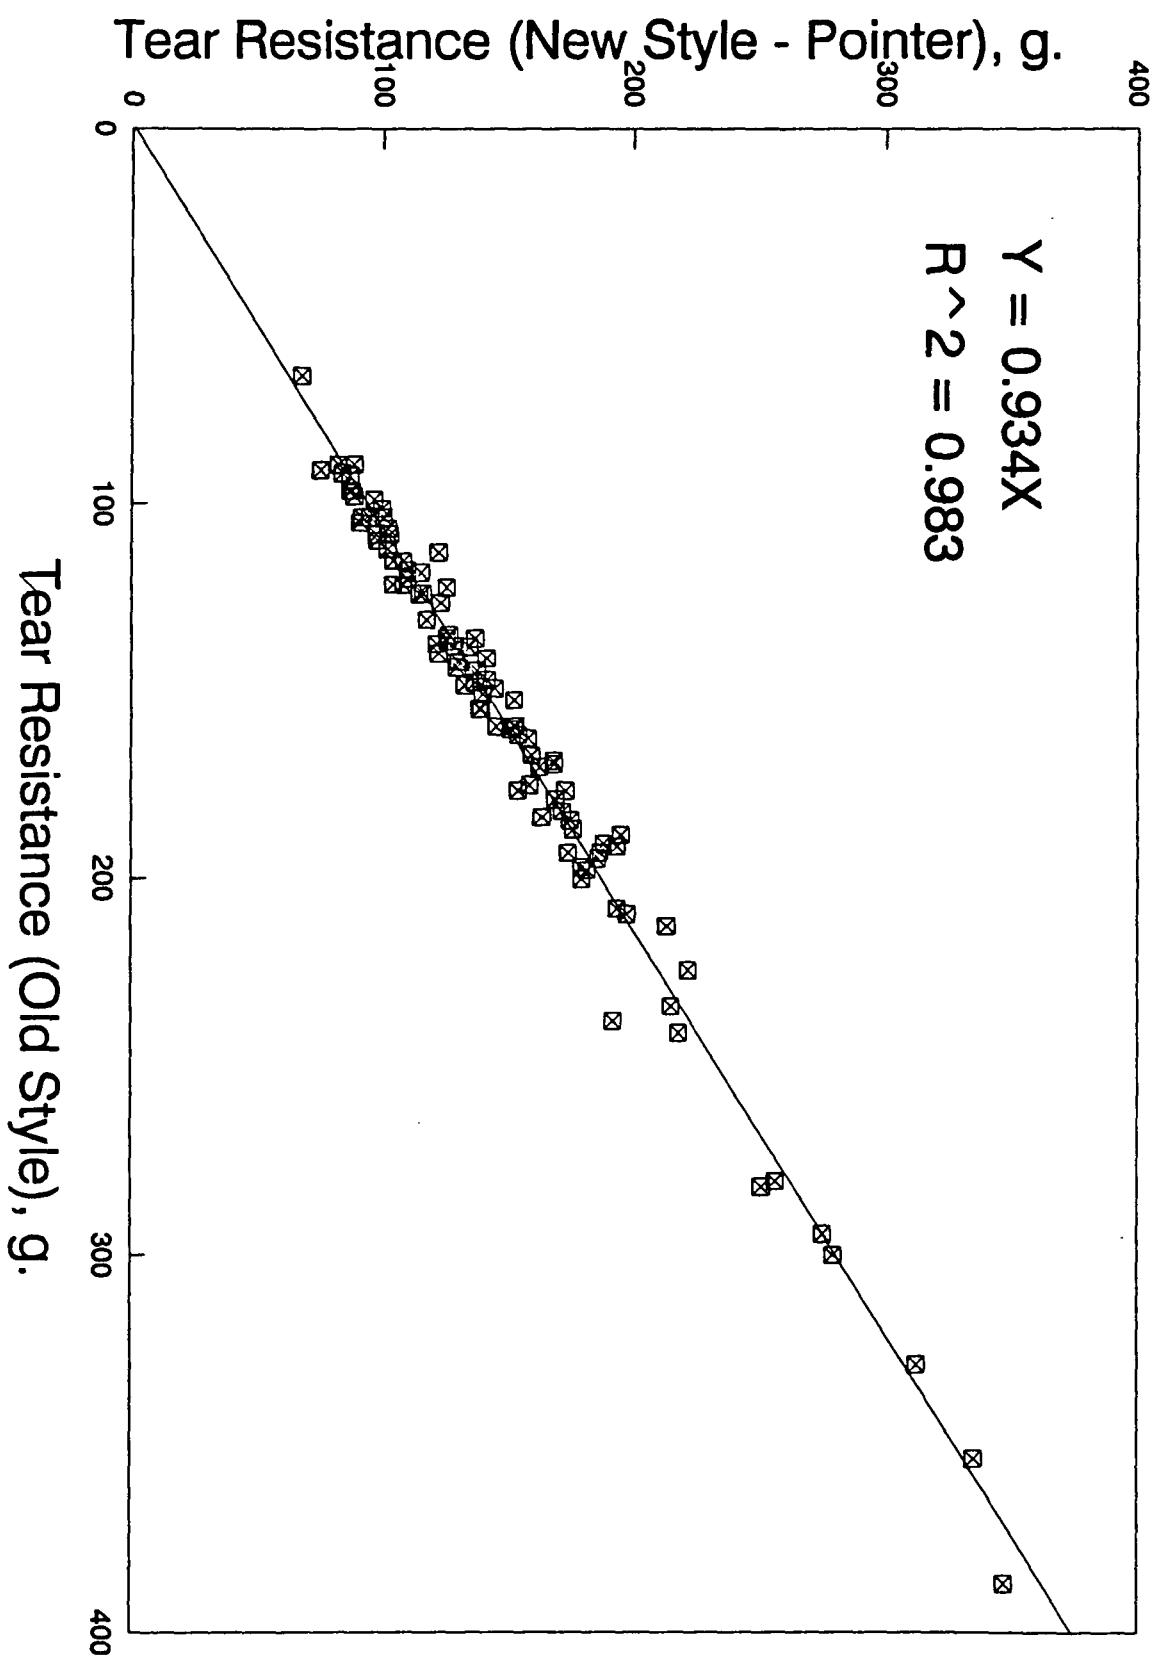

FIGURE 1

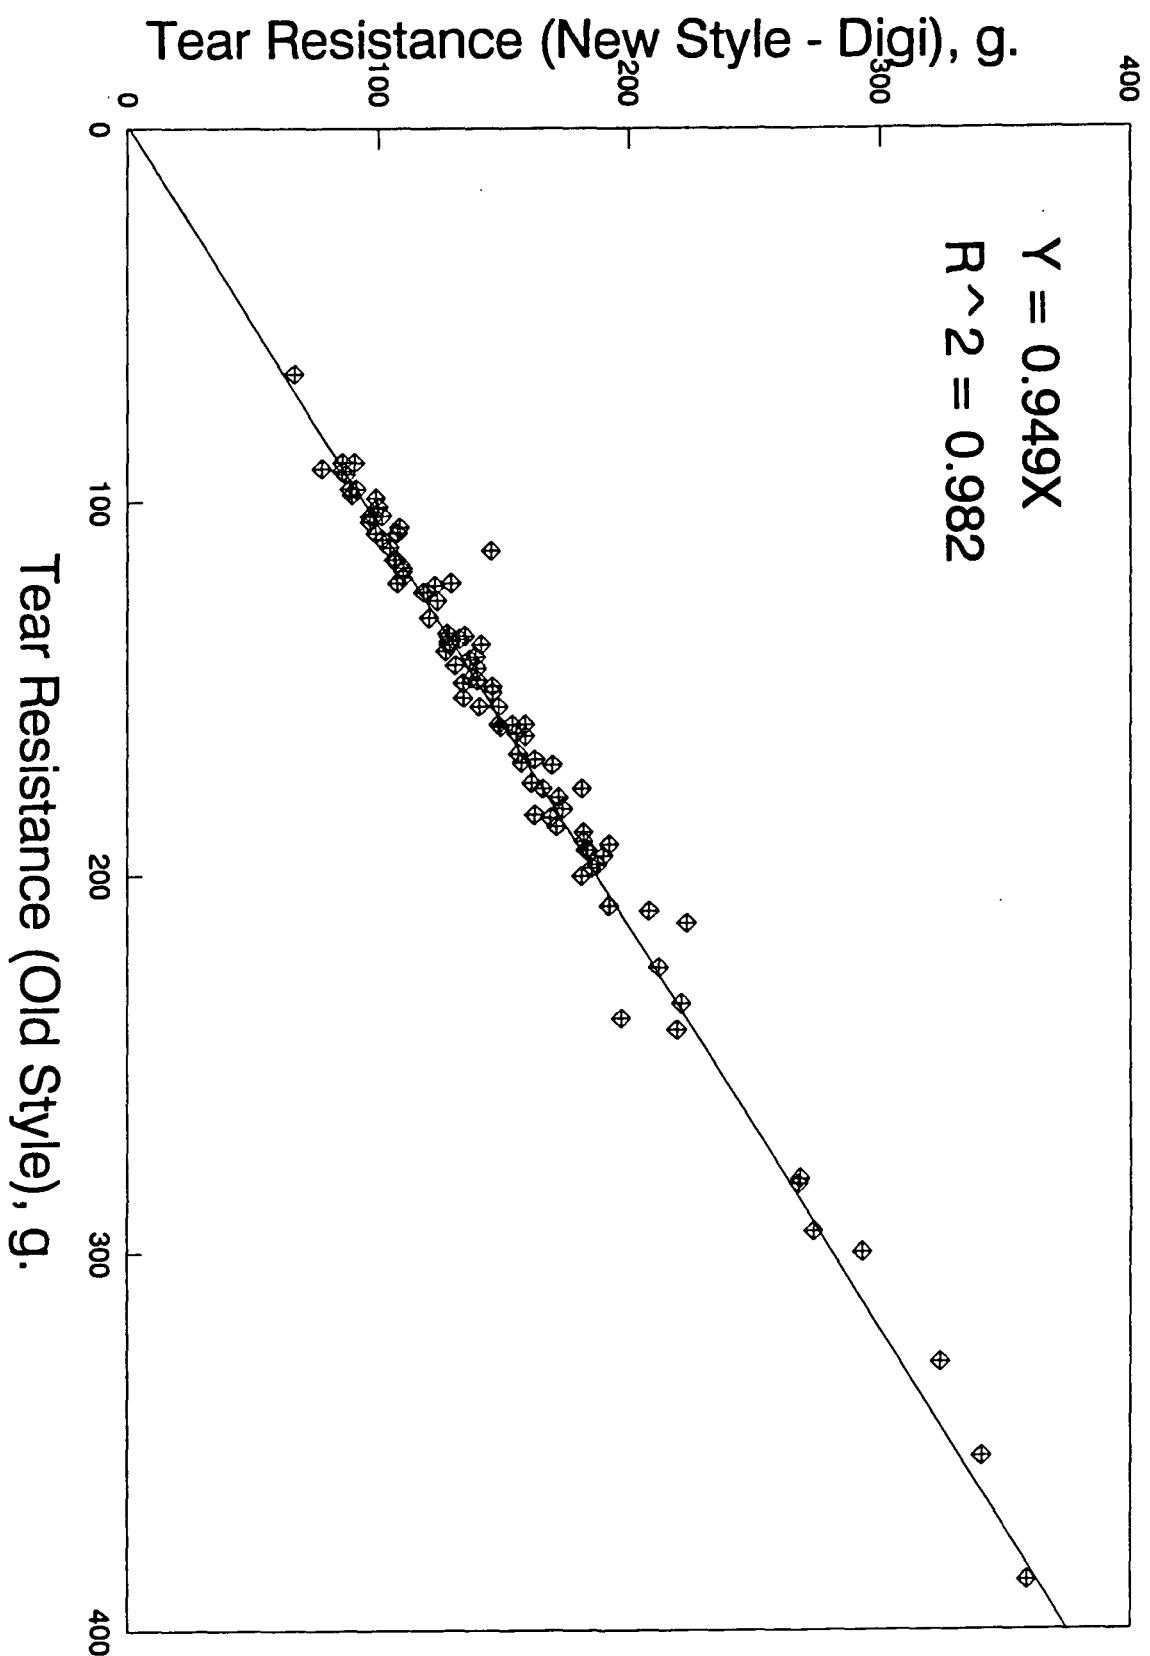

FIGURE 2

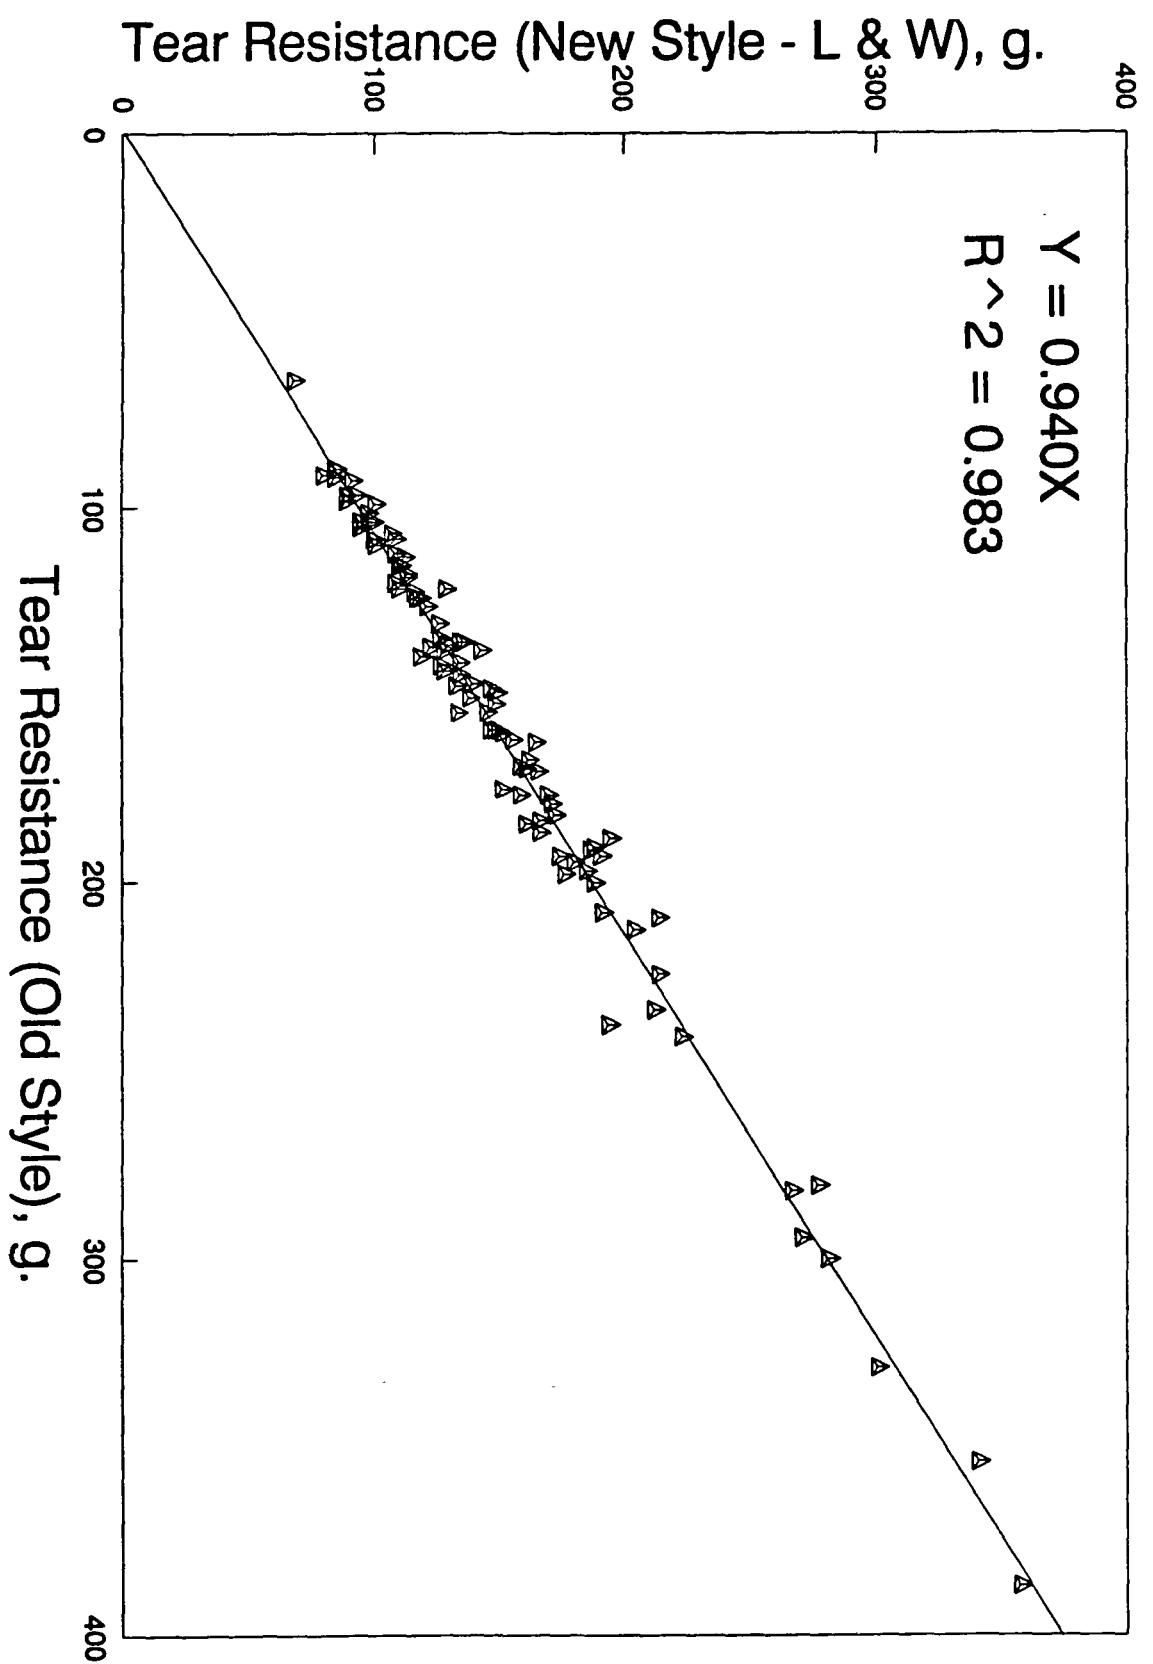

FIGURE 3

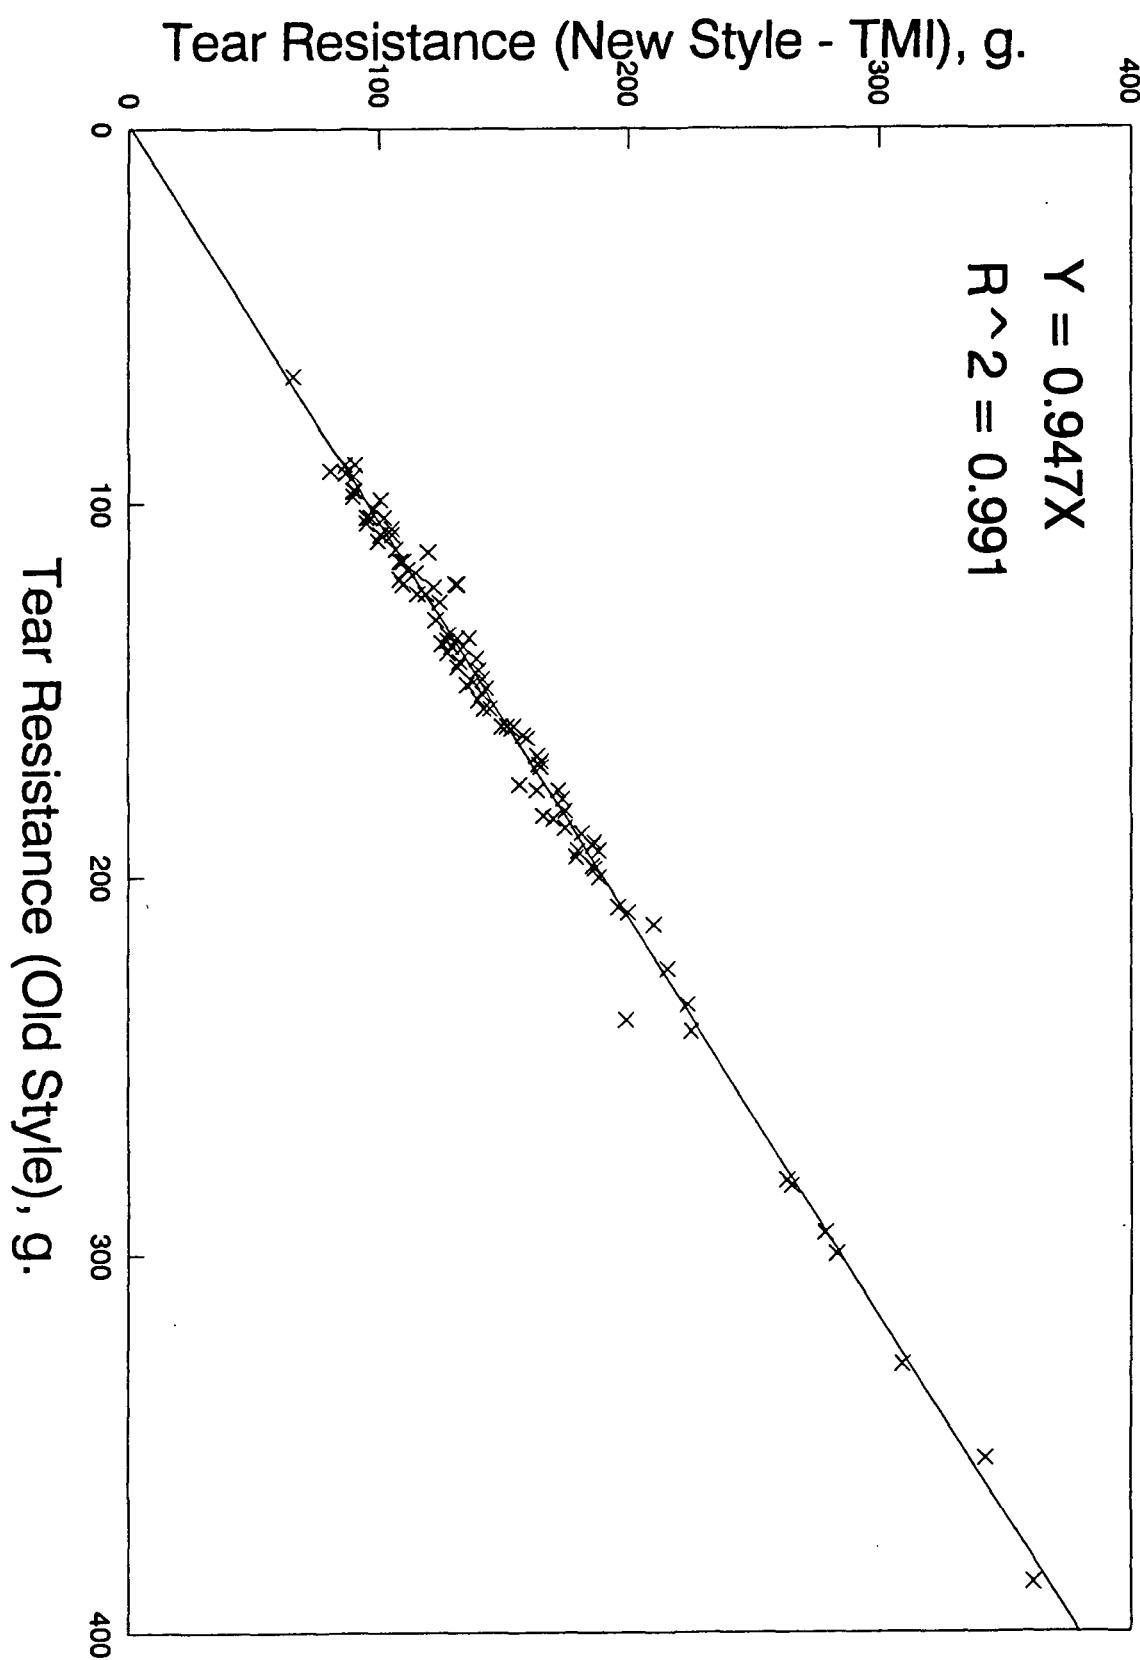

FIGURE 4

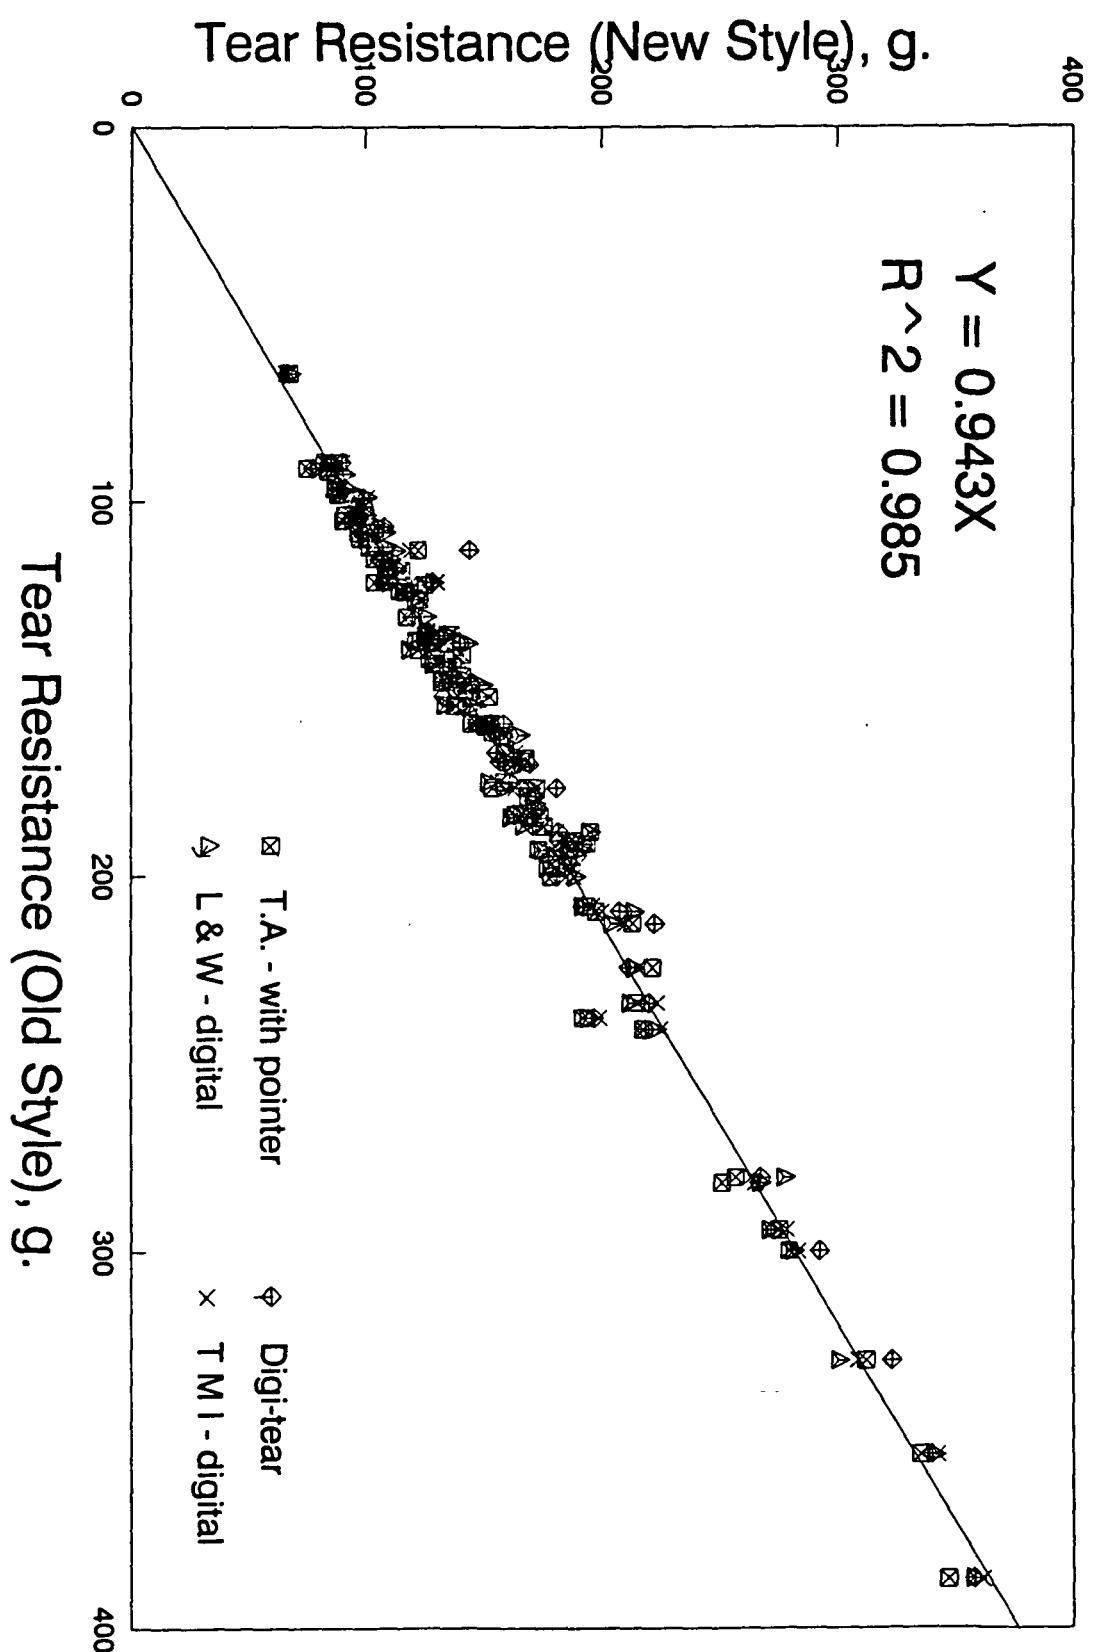

FIGURE 5

An analysis of variance of the tear data was made to determine if correlations between new and old instrument readings must include the effects of paper grade, basis weight, and test direction. The results are given below.

Analysis of Variance For New					
Source	df	Sum of Squares	Mean Square	F-ratio	Prob
Old	1	288068	288068	5802.6	0
TBW	1	57.3640	57.3640	1.1555	0.2852
GRD	1	147.812	147.812	2.9774	0.0878
DXN	1	189.282	189.282	3.8128	0.0539
Error	91	4517.64	49.6443		
Total	95	292980			

Using the normal criterion of 95% confidence, we find only old tear (OLD) to be significant ($p < 0.0001$). However, grade (GRD) has a p value of 0.0878, and direction (DXN) a p value of 0.0539. These deserve further examination, which was done by repeating the analysis after the clearly insignificant factor of basis weight (TBW) was removed. The result (shown below) now indicate that grade and direction have p values of 0.1261 and 0.2988, and can be discarded. Hence, the only significant remaining variable is the old tear value.

Analysis of Variance For New					
Source	df	Sum of Squares	Mean Square	F-ratio	Prob
Old	1	288068	288068	5599.1	0
GRD	1	122.598	122.598	2.3829	0.1261
DXN	1	56.1836	56.1836	1.0920	0.2988
Error	92	4733.31	51.4490		
Total	95	292980			

A subset of the analysis indicated that results obtained with the new style tester equipped with a mechanical pointer were significantly lower than those obtained with testers equipped with digital readout. However, the difference is only about one-half of one percent and is not regarded to be of any practical importance.

Hence, we can conclude that a single coefficient of 1.06 can be used for all instrument types, grades, weight, and test directions. Separately, it was determined that the R^2 parameter was not significantly improved by including an intercept constant.

Tensile Properties.

A summary of the tensile strength results are given in Table 2. Plots of these data are shown in Figure 6.

An analysis of variance of the tensile data indicated a significant grade - direction interaction. Close examination of the data suggested that machine direction results for flat grades needed to be explored separately from the rest of the data. It should also be noted that the machine direction of flat grades has much less stretch than either the cross direction of flat grades or both directions of extensible grades. Separate plots for the low stretch and high stretch samples are shown in Figure 7 and 8 and we conclude that:

1. The MD tensile strengths of flat grades (i.e. samples having relatively low stretch) measured with CRE type instruments are in good agreement with that measured with a pendulum type instrument.
2. The CD tensile strength of flat grades, and that of extensible grades tested in both MD and CD, (ie: samples having a relatively high stretch) are 2.0% lower when tested with CRE instruments than when tested with a pendulum tester.
3. The regressions were not significantly affected by CRE instrument type or by basis weight, and were not significantly improved by using intercept constants.

Tensile results obtained at two different test spans (7.1 and 4.8 inches) are compared in Figure 9. On average, results obtained at a span of 7.1 inch are about 3% lower than those obtained at a span of 4.8 inch.

Elongation related properties (stretch, tensile energy absorption (TEA), and tensile stiffness (Et) were only measured for the constant rate of elongation testers. These results are summarized in Tables 3-5, and Figures 10-12. The data show that stretch measured at a span of 7.1 inch is about 2% lower than that measured at a span of 4.8 inch (Figure 10). TEA is about 4% lower (Figure 11), and Et is about 2% higher (Figure 12).

The standard error of the Y estimate for each of the tensile property graph is tabulated in Table 7.

Figure 13-16 show that test results obtained with the Instron and L & W are in reasonable agreement with each other.

Moisture Content

The measured moisture content for each sample is tabulated in Table 6. The average moisture content for all samples is 7.3%. Comparison of results obtained for different geographic areas (not shown) indicate that the moisture content of bag paper manufactured in East Coast mills is 7.4%, whereas that for paper manufactured in West Coast mills is 7.0%. Presumably this difference is attributable to differences in fiber sources. The average moisture content of 7.3% will be used to calculate adjusted basis weight values for data submitted for the KPPD sponsored baseline program.
