THE INSTITUTE OF PAPER CHEMISTRY

Appleton, Wisconsin

SUMMARY

The objective of the continuous baseline study on linerboard is twofold. The first objective is to provide an indication of the quality of the 42-lb. fourdrinier kraft linerboard being produced by each of the participating mills and by the industry as a whole. The second objective is to provide a procedure whereby the mills have the opportunity to compare their test results with those obtained at the Institute on similar materials, thus providing a convenient system of instrument verification. The first objective is implemented by the weekly sampling of the product of each machine manufacturing 42-lb. kraft linerboard and submitting these weekly samples to The Institute of Paper Chemistry where they are evaluated for basis weight, caliper, bursting strength, and Elmendorf tearing strength. The second objective of the continuous baseline study--namely, to provide a convenient system of instrument verification--is achieved by the testing of analogous samples by the mill and the Institute. The mill data are sent to the Institute, and a comparison of Institute and mill test results is included in the monthly reports. In addition to fulfilling the two prime objectives described above, the baseline study is accumulating an invaluable ever-growing reserve of background information essential for the intelligent evaluation of specifications of any kind.

During the month of June, one hundred sample lots of 42-lb. fourdrinier kraft linerboard representing the production of seventeen mills were evaluated at The Institute of Paper Chemistry. Shown below are the maximum and minimum current mill averages for each test (the current mill average is the average of the results obtained on the sample

lots of linerboard submitted from a given mill); also shown for each test is the current F.K.I. average which is determined by averaging the current mill averages and is indicative of the test level being maintained by the industry as a whole to the degree that the industry is represented by the participating mills:

	Maximum Current Mill Av.	Minimum Current Mill Av.	Current F.K.I. Av.
Basis weight, lb.	44.4	42.9	43.7
Caliper, pt.	14.0	11.6	12.7
Bursting strength, p.s.i. gage	118	106	112
Machine direction, Elmendorf tear, g./sheet	370	284	333
Cross-machine direction, Elmendorf tear, g./sheet	420	338	378

As mentioned previously, the study provides a procedure whereby the mills have the opportunity to compare their test results with those obtained on corresponding sample lots of linerboard at the Institute so that a convenient system of instrument verification is readily available to all participants. A summary of the agreement obtained in the comparisons of Institute and mill test results for the current period is shown below. The tabulated data show the number of mills (and the percentage of all mills which this number represents) whose average test results for the month of June fall within the designated percentages from the average test results obtained at the Institute on corresponding materials.

		Average Percentage Difference Between Institute and Mill Test Results								
		± 1	± 2	± 3	± 4	± 5	± 7.5	± 10	± 15	± 18

INTRODUCTION

The objective of the continuous baseline study on linerboard is twofold. One objective is to provide an indication of the quality of the 42-lb. fourdrinier kraft linerboard being produced by each of the participating mills and by the industry as a whole. Another objective is to provide a procedure whereby the mills have the opportunity to compare their test results with those obtained at the Institute on similar materials, thus providing a convenient system of instrument verification. The first objective mentioned above is implemented by the weekly sampling of the product of each machine manufacturing 42-lb. kraft linerboard and submitting these weekly samples to The Institute of Paper Chemistry where they are evaluated for basis weight, caliper, bursting strength, and Elmendorf tearing strength. The second objective of the continuous baseline study--namely, to provide a convenient system of instrument verification--is achieved by the testing of analogous samples by the mill and the Institute. The mill data are sent to the Institute, and a comparison of Institute and mill test results is included in the monthly reports. In addition to fulfilling the two prime objectives which have been described, the baseline study is accumulating an invaluable ever-growing reserve of background information essential for the intelligent evaluation of specifications of any kind.

The dual objectives of the continuous baseline study on linerboard have been described in the preceding paragraph. The remainder of the report presents the test results for the linerboard samples which were evaluated during the month of June. In line with the dual nature of

the study, the presentation is divided into two parts. Part I presents the results obtained at The Institute of Paper Chemistry, and Part II presents a comparison of results obtained at the Institute with those obtained at the mills. It should be noted that the same code letters are not used to identify the same participants in these reports from month to month. Each participant is privately advised of his own code. Attention is directed to the fact that the bursting strength results presented in these reports have been obtained, beginning in April, with the "new" diaphragm. By "new" diaphragm is meant the composition and style (fillet filled in) introduced by B. F. Perkins and Son, Inc. The same diaphragm distension characteristics, namely, 40-45 p.s.i. at 1.8 cm. distension were used; however, it was necessary to change diaphragms far more frequently than with the old style and composition diaphragm.

PART I: PRESENTATION AND DISCUSSION OF RESULTS OBTAINED AT
THE INSTITUTE OF PAPER CHEMISTRY

During the month of June, one hundred different sample lots of 42-lb. fourdrinier kraft linerboard from seventeen different F.K.I. mills were processed at The Institute of Paper Chemistry. A tabulation of the number of samples classified according to mill may be seen in Table I.

These sample lots were tested for basis weight, caliper, bursting strength, and Elmendorf tear. The average strength results for each mill may be seen in Table II and are graphically presented in Figures 1 to 5. In addition to a comparison of the current mill averages for the various tests, Table II also shows the current F.K.I. averages, the cumulative F.K.I. averages, and the F.K.I. indexes. The current F.K.I. average represents the average of the current mill averages whereas the cumulative F.K.I. average represents the average of the current F.K.I. averages for the previous twelve months excluding the current period. Hence, in the case of the current report, the cumulative F.K.I. average covers the period from June 1, 1959 to May 31, 1960. The F.K.I. indexes are obtained as follows:

$$\frac{\text{current F.K.I. average}}{\text{cumulative F.K.I. average}} \times 100 = \text{F.K.I. index (\%)}$$

The F.K.I. index provides a ready means of comparing the current quality with previous results. For example, the current F.K.I. average basis weight is 43.7 lb., and the cumulative F.K.I. average basis weight is 43.5 lb. Hence, the F.K.I. index for basis weight determined in percent as previously described is 100.5 and indicates that the current F.K.I. average basis weight is slightly higher than the cumulative F.K.I. average.

A comparison of the current mill averages in Table II and Figure 1 shows that the average basis weight results for all mills conform to the 42-lb. specification set forth in Rule 41. Mill K had the highest average basis weight of 44.4 lb. which was approximately 5.7% higher than the 42-lb. specification. The lowest average basis weight of 42.9 lb. was shared by Mills A and N.

The amount by which the mills vary from the 42-lb. specification is shown in Table II-A.

A comparison of the current F.K.I. basis weight average for this period with that for the previous period shows that basis weight has increased from 43.6 lb. to 43.7 lb.

A comparison of the average caliper values for the various mills (see Figure 2) shows that the current mill averages varied from a low of 11.6 points for Mill C to a high of 14.0 points for Mill A. The current F.K.I. caliper average was 12.7 points, which was the same as the cumulative F.K.I. average.

The average bursting strength values given in Table II for each mill are graphically presented in Figure 3. It may be observed in Table II and Figure 3 that the current mill averages for bursting strength ranged from a low of 106 for Mill G to a high of 118 for Mill C. The current F.K.I. bursting strength average was 112 p.s.i. gage, which was higher than the cumulative F.K.I. average of 109.

TABLE II-A

N	+2.1
O	+4.5
P	+3.1
Q	+3.1
S	+4.5
T	+4.5

The Elmendorf tear results shown in Table II for the various mills are presented graphically in Figures 4 and 5. From these presentations it may be observed that Mill T had the highest machine direction tear average of 370 g./sheet, and Mill G had the lowest average of 284 g./sheet. It may be further noted that the highest cross-machine direction tear average of 420 g./sheet was associated with Mill T and that the lowest average of 338 g./sheet was associated with Mill G. It may be observed also in Table II and Figures 4 and 5 that the current F.K.I. averages for machine direction and cross-machine direction Elmendorf tear are slightly higher than their respective cumulative F.K.I. averages.

A comparison of the F.K.I. indexes indicates that, for the current period, the current F.K.I. averages for basis weight, bursting strength, machine direction, and cross-machine direction Elmendorf tear are slightly higher than their respective cumulative F.K.I. averages, and the current F.K.I. average for caliper is the same as the cumulative F.K.I. average.

In order to compare the variation within a given mill, the test results for the participating mills have been tabulated in Tables III to XXI alphabetically. In addition to the current and cumulative average, a mill factor and mill index are given for each mill. The current mill average represents the average test result obtained for all samples evaluated during the current period. The cumulative mill average for each test, on the other hand, represents the average of the current mill averages for the previous twelve months excluding the current period. The mill factor and the mill index are obtained as follows:

$$\frac{\text{current mill average}}{\text{cumulative mill average}} \times 100 = \text{mill factor (\%)}$$

$$\frac{\text{current mill average}}{\text{cumulative F.K.I. average}} \times 100 = \text{mill index (\%)}$$

The mill factor and the mill index are a convenient means for comparing the current mill results either with the previous results for that particular mill or with the cumulative F.K.I. results. The reports also present a comparison of the test data obtained at the mills with test data obtained at The Institute of Paper Chemistry. These test data are presented and discussed on subsequent pages of this report.

It may be noted in Tables III through XXI that information is included about the sheet finish. A review of the tables for the mills which supplied this information indicates that some kind of water finish is being used by all.

PART II: COMPARISON OF RESULTS OBTAINED AT THE INSTITUTE OF
PAPER CHEMISTRY WITH THOSE OBTAINED AT THE MILLS

As a supplementary part of the Continuous Baseline Study, comparisons of the mill test results with those obtained at The Institute of Paper Chemistry on corresponding samples have been included in this report. Mill test conditions are shown in Table XXII, where it may be noted that the atmospheric conditions used prior to and during the testing period were relatively uniform for the mills which reported this information. However, the preconditioning and conditioning time periods varied considerably.

A summary of the Institute and mill test results for the current period is shown in Table XXIII, and a comparison of percentage differences between Institute and mill test results is given in Table XXIV for the current period and the two previous periods.

A comparison of the test data in Tables XXIII and XXIV reveals the level of agreement between mill and Institute data for basis weight, caliper, bursting strength, and Elmendorf tear. In Table XXIII the over-all average difference between Institute and mill results is shown for each of these tests based on the data for all sample lots submitted by each mill for the current period. In addition, the maximum difference encountered in comparing the Institute and mill test results for a given sample lot is shown. In Table XXIV, the over-all average differences shown for each test in Table XXIII have been calculated on a percentage basis for each mill. In addition, for purposes of comparison, the average percentage differences for the preceding two periods are shown.

TABLE XXII
PRECONDITIONING AND CONDITIONING DATA FOR MILL TESTS

* Comparison based on averages involved only those samples on which mill test data were submitted.

** Average difference is the difference between the Institute mill average and the mill average based on mill test data.

*** Maximum difference encountered in comparing the Institute average and the mill averages for any sample submitted by that particular mill.

COMPARISON OF INSTITUTE-MILL DIFFERENCES BY PERIODS Average Difference. Per Cent

It may be noted in Table XXIV that for the current period the largest average percentage difference between the average basis weight results of the Institute and those of a given mill on corresponding samples was three per cent. By comparison, the largest average percentage difference noted for the previous two periods was also three per cent. Further, it may be noted that the average basis weight results for Mills A and Q were higher than those for the Institute and the average result for Mill L was the same as that for the Institute, and the results for the other mills were lower than the corresponding results for the Institute. In general, agreement between Institute and mill basis weight results was good.

The maximum variation in caliper for the current period was seven per cent. This was higher than the maximum variation of five per cent for the previous two periods. Compared with the Institute's results, the average test result for Mill L was higher, and the average test results for the other mills were lower. Agreement was good for the majority of comparisons of Institute and mill caliper results. The difference noted for Mill P appeared to be excessive.

It may be noted in Table XXIV that the bursting strength results exhibited a maximum variation of four per cent for the current period. The maximum variation for the two preceding periods was nine per cent. The average bursting strength results for Mills F, Q, and S were the same as the corresponding results for the Institute, the average results for Mills B, G, K, and P were higher than those for the Institute, and the average results for the other mills were lower. Agreement between Institute and mill results was very good.

It may be seen in Tables XXIII and XXIV that the average machine direction tear results for Mills A, F, K, L, N, and Q were higher than those for the Institute, the average result for Mill O was the same as that for the Institute, and the average results for the other mills were lower. The maximum variation for the current period was eighteen per cent compared with a maximum variation of twenty-one per cent for the two preceding periods. Agreement between the Institute and mill results was generally good. However, the variations for Mills E, H, K, and P appeared to be excessive.

With regard to the cross-machine direction tear results, it may be noted that the average results for Mills A, F, G, J, K, L, M, N, and Q were higher than those for the Institute, and the average results for the other mills were lower. The maximum variation for the current period was eleven per cent, which was slightly lower than the maximum variation of fourteen per cent for the two preceding periods. As in the case of the machine direction results, agreement between Institute and Mill results was generally good. However, the variations for Mills H, J, and L appeared excessive.

The comparisons of Institute and mill data for individual sample lots are given alphabetically in Tables XXV to XLIII for the various mills. In all the comparisons given in Tables XXV to XLIII, the Institute's test values have been used as the reference line.

The reader's attention is directed to page 3 of this report where the comparison of Institute and mill test data is summarized to show the number of mills (and the percentage of all mills which this number represents) whose average test results for the month of June fall within designated percentages from the average test results obtained at the Institute.

Current Mill Average:				43.9	42.8	-1.1	13.2	12.8	-0.4	110	109	-1	370	420	

aThis average includes the readings for one or more specimens which tore beyond the 3/8-inch limit.

Note: All "current mill average" data are calculated from the totals of the individual readings.
