

Bimetallic Machining

Precision Manufacturing Research Consortium
Industrial Advisory Board
Georgia Institute of Technology
29 October 1997

Scott Billington
Marc Crudele
Advisor: Dr. Tom Kurfess

Goal and Motivation

- ❖ To examine the process of milling bimetals and vary experimental parameters in order to determine statistically significance factors in achieving a superior surface finish.

Examples of Bimetallic Machining

- ❖ Steel sleeves in aluminum engine blocks
- ❖ Machining over welds
- ❖ Aluminum space frames with steel joints
- ❖ Composite space frames with metallic joints
- ❖ Interrupted cutting (air and metal)

Items of Investigation

- ❖ Up-milling versus Down-milling
- ❖ Impact order
- ❖ Variation of material removal effects
- ❖ Vibrational characteristics

RMS Surface Measurements

Present Conclusions

- ❖ The softer the first material, the better the surface finish of the second
- ❖ The more material removed from a harder first material the worse finish there is on a softer second material
- ❖ A larger magnitude in vibration does not necessarily produce a worse surface finish

Future Work

- ❖ More vibrational measurements of process
- ❖ Cutting force measurements
- ❖ Effects of tool parameters (rake, edge radius, etc.)
- ❖ More advanced analysis of surface finish (microscopic analysis)
- ❖ Three dimensional metrology of surface
