This thesis is dedicated to my wonderful and always supportive family. My beautiful wife, Katie, whose encouragement and love I treasure above all else. Her calming influence and unselfish support kept me focused throughout the school year. My daughters, Abby and Anna, are immeasurable fun and remind me to put the books down and enjoy life.

ACKNOWLEDGEMENTS

Thank you to Dr. Daniel Schrage for his guidance over the past two years. I appreciate your encouragement to study a topic unique to rotorcraft design and your efforts in providing a wealth of resources to accomplish the task.

Thank you to the Committee member's Dr. Sanborn and Dr. Mavris, and all of the professors I have studied under. Their expertise and recommendations proved invaluable in the completion of course work and this thesis.

I am grateful to Dr. Robert Handschuh of the Vehicle Technology Directorate at the NASA Glen Research Center for providing resources on the Mi-26 split torque transmission and sharing his insight into the future of heavy lift rotorcraft.

Lastly, thank you to my fellow graduate students for outstanding teamwork in projects and in studying for exams. Thank you to Alex Moodie for tutoring me in the use of Model Center and system modeling.

SUMMARY

The transformation of Joint forces to be lighter, more lethal, and capable of deploying from multiple dispersed locations free of prepared landing zones will widen a capability gap that cannot be met by the current fleet of Joint aircraft. In order to close this capability gap, a dedicated heavy lift VTOL aircraft must rapidly deliver large payloads, such as the 20 to 26 ton Future Combat System, at extended ranges in demanding terrain and environmental conditions.

Current estimates for a single main rotor configuration place the design weight over 130,000 pounds with an installed power of approximately 30,000 horsepower. Helicopter drive systems capable of delivering torque of this magnitude succeeded in the Russian Mi-26 helicopter's split-torque design and the Boeing VERTOL Heavy Lift Helicopter (HLH) prototype's traditional multi-stage planetary design. The square-cube law and historical trends show that the transmission stage weight varies approximately as the two-thirds power of torque; hence, as the size and weight of the vehicle grows, the transmission's weight becomes an ever-increasing portion of total gross weight. At this scale, optimal gearbox configuration and component design holds great potential to save significant weight and reduce the required installed power.

The presented drive system design methodology creates a set of integrated tools to estimate system weight and rapidly model the preliminary design of drives system components. Tools are provided for gearbox weight estimation and efficiency, gearing, shafting, and lubrication and cooling. Within the same architecture, the designer may add

xxii

similar tools to model subcomponents such as support bearings, gearbox housing, freewheeling units, and rotor brakes.

Measuring the relationships between key design variables of these components and system performance metrics reveals insight into the performance and behavior of a heavy lift drive system. A parametric study of select design variables is accomplished through an intelligent Design of Experiments that utilizes Response Surface Methodology to build a multivariate regression model. The model permits visualization of the design space and assists in optimization of the drive system preliminary design.

This methodology is applied to both the Boeing HLH and the Russian Mi-26. Both designed in the late 1970's, the tandem rotor HLH fails to take full advantage of the tremendous benefits gained by dividing the input torque into multiple, high speeds paths and then recombining the split paths at the final stage. The Mi-26 has successfully employed a split torque gearbox in the field for over 20 years. This study applies the drive system design methodology to compare the split-torque gearbox over a multi-stage planetary gearbox in a single main rotor heavy lift helicopter.

SCOPE

The scope of this thesis includes the furnished single main rotor baseline design and drive system requirements, drive system configuration for a multi-stage planetary main gearbox and a split-torque main gearbox, weight estimation, and preliminary design tools for the following drive components:

- 1. Gearboxes
- 2. Shafting
- 3. Gearbox cooling
- 4. Accessory accommodation

A designer has the freedom to incorporate additional analysis into the model. Some recommended elements that should be included for a complete preliminary design include:

- 1. Bearings
- 2. Housing
- 3. Keyways
- 4. Seals
- 5. Couplings
- 6. Structural integration

7. Failure warning and health systems The thesis obtains the impact of excursions through a Design of Experiments (DoE) and utilizes Response Surface Methodology (RSM) to explore the response behavior of the drive system through the

design space defined by excursions (E1, E2, E4, E5, and E6). The thesis limits the study to:

- 1. Single main rotor helicopter
- 2. Specified design space
- 3. Simplified rotor loads
- 4. Accessory accommodation

MOTIVATION

Need for a Joint Heavy Lift Helicopter

The military and commercial industries have great need for a heavy lift VTOL aircraft capable of transporting large payloads over longer distances and at a high rate of speed. Current transport fixed wing aircraft require large runways and support facilities, thus severely restricting a military commander's or commercial operations officer's freedom. The heavy lift VTOL aircraft fills a capability gap by providing heavy lift capability at high speeds independent of large runways.

For the military, the transport of large payloads is possible with fixed wing aircraft such as the C-130, C-141, or C-5. These assets, however, have their limitations as they are tied to fixed-base operations and large runways. A commercial airline experiences the same trade off within its fleet of commercial transport airplanes. The modern V-22 achieves a new degree of freedom through its vertical take-off capability and high-speed cruise though it cannot lift large payloads. The largest heavy lift helicopter in the world, the Mi-26, is capable of transporting the requisite 20-ton payload but is restricted from shipboard operations and reaches only 150 knots. There is not an aircraft in existence that can couple the freedom gained by VTOL, a high cruise speed, and a high payload capacity.

This mission is further detailed in the Draft Version 6.1 of the Initial Capabilities Document of the Joint Heavy Lift (JHL) Supplemental Package and is summarized by the associated Statement of Objectives:

"The JHL is expected to overcome enemy anti-access strategies, execute joint-enabled operational maneuver, and leverage sea basing in order to expand Expeditionary Maneuver Warfare capabilities. It [JHL] is also expected to achieve positional advantage to maintain operational momentum; enable SOF infiltration & exfiltration operations; conduct mounted and dismounted vertical envelopment; and perform aerial delivery operations."¹

The military is searching for new ways to provide a rapid, flexible response in a hostile environment without being dependent upon runways. Furthermore, the military is looking for a way to bypass traditional points of embarkation in exchange for the flexibility to operate directly from ships. The overall goal is to transport light combat vehicles at payloads, ranges, and speeds beyond what is considered feasible for traditional helicopters. The heaviest payload includes the Future Combat System (FCS) at a weight of 20-26 tons (see Figure 1). Despite the Mi-26's success, there exists no shipboard capable rotorcraft with the payload capacity, cruise speed and range to accomplish this mission.

Square Cube Law

The square-cube is a mathematic principle of proportion that is often applied to engineering and biomechanics. The square-cube law states "when an object undergoes a proportional increase in size, its new volume is proportional to the cube of the multiplier and its new surface area is proportional to the square of the multiplier."² This proportional increase is illustrated in Figure 2.

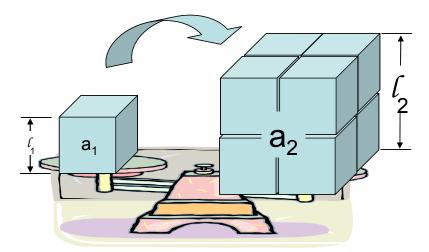

Figure 2: Square Cube Law Block

Relating volume to area will mathematically express this law as:

$$v_2 = v_1 \left(\frac{\lambda_2}{\lambda_1}\right)^3$$
 and $a_2 = a_1 \left(\frac{\lambda_2}{\lambda_1}\right)$

Equation 1

where

 l_1 is the original length and l_2 is the new length v_1 is the original volume and v_2 is the new volume

² Wikipedia website, http://en.wikipedia.org/wiki/Square-cube_law, 1 August, 2005.

 a_1 is the original surface area and a_2 is the new surface area

For example, if the length, l_1 , of a cube shown in Figure 2 is doubled in length to l_2 , the cube's surface area is increased by 2^2 or by a factor of 4. For volume, if l_2 is doubled, then volume increases by 2^3 or 8 times the cube's original volume.

By equating the expressions in Equation 1 and considering constant material, uniform density, and constant speed (for rotating components such as gears, shafts, and bearings) the square-cube law may be expressed as:

$$W_2 = W_1 \left(\frac{T_2}{T_1}\right)^{3/2}$$

Equation 2

where

 W_1 is the original weight and W_2 is the new weight T_1 is the original torque and T_2 is the new torque required

This relationship has a tremendous impact on the engineering of structures and mechanical systems such as mechanical power transmitting drive trains. As the size or torque transmitted of the drive system increases, the system mass will outpace the torque change at an exponential rate. This application of the square-cube law provides a general guideline to the resizing of mechanical systems as a function of the torque of 1.50 (Equation 2). In fact, the AMCP 706-201 predicts new gear stage weight as a power of 1.43.³

³ Headquarters, U.S. Army Material Command, <u>AMC Pamphlet 706-201 Engineering Design Handbook:</u> <u>Helicopter Engineering (Part One: Preliminary Design)</u> (Alexandria: GPO, 1974), 4-66.

The AMCP approximates gear stage weight as:

$$W_{stage_2} = W_{stage_2} \left(\frac{T_2}{T_1}\right)^{1.43}$$

Equation 3

According to the AMCP, the change in shafting weight is an even more dramatic power of 2.63:

$$W_{shaft_2} = W_{shaft_2} \left(\frac{T_2}{T_1}\right)^{2.63}$$

Equation 4

An increase in weight against the change in torque required is shown graphically for Equation 2, Equation 3, and Equation 4 in Figure 3.

At higher and higher relative torque, a drive system grows enormous in size and especially weight. If carried to the extreme, the size of a system will reach a practical limit where the system will be unable to support itself and buckle under its own massive weight. Such limits are common in the civil engineering of a skyscraper's structure. For aerospace engineering, the aircraft structure or drive system may never reach such an extreme point, but the design will certainly reach a practical limit where the generated lift cannot sustain flight of the aircraft's large gross weight.

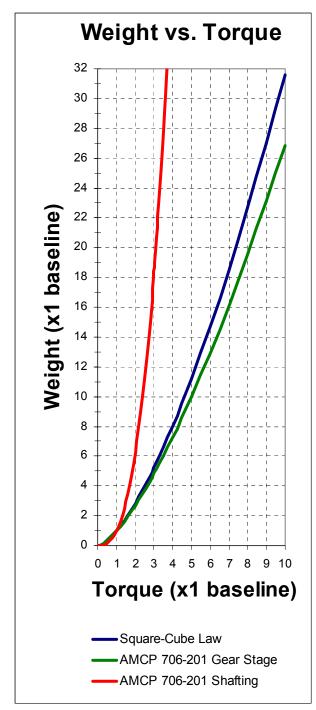

Figure 3: Square-Cube Law Predictions of Weight verse Torque

<u>The Importance of Heavy Lift Drive Systems</u>

Current estimates for a single main rotor heavy lift configuration place the design weight over 130,000 pounds with an installed power of approximately 30,000 horsepower. At such high gross weights and loads, the drive system becomes an everincreasing percentage of the aircraft gross weight.

For heavy lift rotorcraft and drive systems, increasing total lift exacerbates this exponential weight increase. To generate sufficient lift, the rotorcraft requires a larger power plant and either more lifting rotors or larger rotor blades. Either condition increases drive system weight. Adding more rotors is an alternative method to avoiding high single torque values and excessively heavy components; however, much of this benefit is lost by duplicate gearing and heavy cross shafting.

Increasing the rotor blade radius presents a different set of problems in the quest for additional lift. With the tip speed of rotor blades fixed constant by compressible flow limits, a larger rotor demands slower rotor rotational speed (rpm). Slower rotational speed requires a greater drive system reduction ratio and results in higher torque values at the end of the drive train. Drive systems capable of higher torque values demand larger and heavier gears, shafting, and bearings. Dividing the torque into multiple paths and combing the torque at the end of the drive train may avoid a portion of this gear and shafting weight gain. Such a system is called a split-torque design and is explored in this study as an alternative to traditional planetary gearing. Despite the benefits of a splittorque, a final reduction to the slower rotation speed is inevitable. Split-torque designs cannot eliminate the heavy gearing and support bearings at the last stage but may lessen the severity of the total system weight gain.

9

The use of face gearing to combine the split torque paths, however, does hold promise to further mitigate the weight gain in the last stage. Unfortunately, the gearing community has yet to standardize face gear stress formulas⁴—removing face gear drives from consideration for this preliminary design model. Despite the current immaturity of face gear standardization, an optimized split-torque drive utilizing spur and bevel gears still holds great potential to save significant weight and reduce the required installed power.

JHL BASELINE

As part of the JHL's Concept Design and Analysis (CDA) effort, the government has solicited industry to assist in "the conceptual design of a baseline VTOL platform configuration and the exploration of the technical trade space associated with that concept."⁵ The CDA's focus is on "the substantiation of viable design concepts" within the desired trade space that "have a reasonable chance of achieving TRL 6 by 2012."⁶ The aircraft's trade space shall meet the desired capabilities described in the Draft Initial Capabilities Document (ICD) and the design flight profile as defined in the Model Performance Specification (MPS). Additionally, the CDA will assess the impact of a set of excursions from the design baseline. This thesis strives to provide insight into the performance and behavior of a heavy lift drive system within the CDA bounds.

Government Furnished Baseline

To assist in the CDA development and to provide a common starting point, the government has furnished conceptual sizing and performance data for a single main rotor helicopter configuration (extracted information relative to the thesis is included in APPENDIX A: JHL SUPPLEMENTAL PACKAGE EXTRACTS). The work of this

study is to provide a preliminary design and optimization of the drive system as defined by the furnished single main rotor baseline. This baseline aircraft is a traditional single main rotor helicopter design with a five-bladed main rotor and classic anti-torque tail rotor as shown in Figure 4.

Figure 4: Single Main Rotor JHL⁷

The power plant consists of three scaleable turbine engines with the drive system combining engine torque at the main gearbox. A long, segmented shaft transmits torque to the tail rotor intermediate gearbox that supplies a direction change at the base of the

Design Excursions

Seven design excursions or alternate sizes from the baseline shall assist in the understanding of varying user design requirements. The purpose of the excursions is to provide trade space information to assess the impact of changing user requirements. The design excursions vary one mission parameter at a time (underline variables represent the baseline design values):⁹

- 1. Design Payload Excursion: 16 ton, 20 ton, 26 ton
- 2. Design Radius Excursion, 210 nm, 250 nm, 400 nm, 500 nm
- 3. Design Hi/Hot Excursion: <u>4,000'/95°F</u>, 6,000'/95°F

These excursions serve as the basis to the formulation of the design space for the drive system design in this thesis. The seven excursions are summarized in Table 1 and Table 2 below. Further information is in found throughout APPENDIX A: JHL SUPPLEMENTAL PACKAGE EXTRACTS and especially in Table 23 and Table 24.

The baseline, E1, E2, E3, E4, E5, and E6 provide valid trade space on changing payload, radius, and hi/hot atmosphere. For simplicity, the study will omit excursions E2A (larger cargo box) and E7 (shipboard capable), as it does not measure payload, radius, or atmospheric performance. E3 is also excluded, as sufficient data is unavailable.

Design Space

The Joint Heavy Lift Supplemental Package provides sufficient information to establish a baseline drive system specific design space. Data arises from the tables in APPENDIX A: JHL SUPPLEMENTAL PACKAGE EXTRACTS or from calculations from the same data. A few calculations are:

- 1. A constant tip speed of 725 ft/s and rotor diameter allowed the calculation of the main rotor speed.
- Main rotor thrust is the product of the constant disc loading at 12.3 lb/ft² and the provided effective disk area.
- 3. An examination of the scaleable NASA high tech turbine engine for heavy lift gave an approximate speed range from 10,000 to 20,000 rpm.

Italics indicate estimates.

When data was lacking, estimated values were selected to best represent a feasible range. Estimates originate from a comparison to other aircraft (mainly the Boeing HLH and Mi-26), extrapolation using the square cube law, and engineering judgment. The design space as shown in Table 3 established the bounds for the analysis conducted in the remaining sections.

ASSUMPTIONS

Major assumptions for the thesis include:

- 1. Scaling for aircraft excursions follows square-cube law
- 2. Design space extremes are in appropriate and valid ranges
- Reference Heavy Lift NASA High Tech Engine deck for engine output speed
- 4. Tail rotor tip speed equals main rotor tip speed (725 ft/s)
- Design of excluded components (bearings, splines, keyways, seals, etc) does not significantly impact the transmission design
- 6. Estimate accessory power requirements
- 7. Simplified model for rotor loads on main and tail rotor drive shafts
- 8. Detailed geometry complies with baseline drawings
- 9. Shipboard compatible and folding/stowage shall not impact drive system design with the exception of a rotor brake
- 10. Main rotor and tail rotor shafts are nonuniform while all others are uniform with bearings to absorb loading

METHODOLOGY

Design Process

The preliminary design and optimization is a three step process (Figure 6) of:

- 1. Drive System Configuration
- 2. Drive System Weight Estimate
- 3. Capture Responses and Conclusions

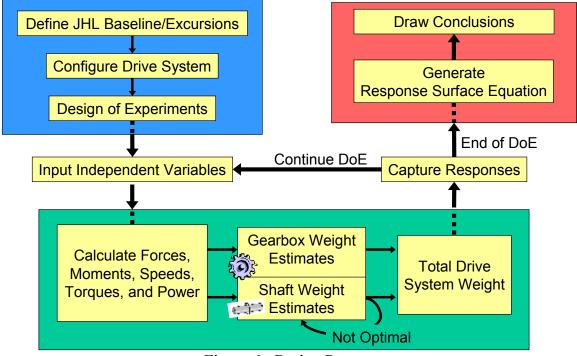

Figure 6: Design Process

The first step, Drive System Configuration (upper left box), involves defining the supplied Single Main Rotor (SMR) JHL configuration. Associated with this is a

component layout to include selection of gearboxes and shafting connecting gearboxes. Next, a screening test selected the major design parameters that most influence the drive system behavior. Once identified, the combinations of key design parameters constitute a Design of Experiments (DoE). Each independent design parameter is varied within the defined design space and in accordance with the DoE.

The middle step (shown as a bottom box), models the actual drive system response for a particular set of inputs. The Weight Estimates section contains three drive system weight estimate methods (modified solid rotor volume, Boeing-Vertol, and Research Technology Laboratories). Here, a designer has the option to model all drive system components similar to the gearing, shafting, and gearbox cooling tools in the Appendices. The accuracy of the weight estimates and the integration of each toolbox to provide a functional, weight-optimized design is the most crucial step in generating realistic solutions.

The final step, Capture Responses and Conclusions (upper right box), captures the output responses for each configuration and uses Response Surface Methodology to determine system behavior. For every set of design parameters, output responses for the solution shall be captured and used to generate a Response Surface Equation (RSE). With the RSE constructed, a family of optimized solutions maybe provided for the drive system. The RSE shall also enable the design to quickly evaluate the impact of changing design parameters through the design process. The accuracy of the weight RSE maybe judged against the two well establish weight estimates as well as compared to similar aircraft like the Mi-26 or CH-53.

<u>Methodology for the JHL</u>

According to Lynwander, "the function of a gearbox is to transmit rotational motion from a driving prime mover to a driven machine."¹¹ In the case of a helicopter, the driver is one or more turbine engines and the driven members include lifting rotors, anti-torque device, and any mechanically driven accessories. A drive system is composed of a series of gears linked together by shafting, supported by bearings, enclosed and mounted by housing, and lubricated and cooled by oil.

The following key principles support the drive system design:

- 1. Transmission loads are a function of power and speed: (T = HP/rpm)
- 2. Input rpm is fixed by output speed of engine
- 3. Rotor speed is a function of blade tip speed and rotor diameter
- 4. Best to take largest reductions in the final stage

Most of the transmission elements can be broken down into:

- 1. Gears
- 2. Shafting
- 3. Bearings 🥥
- 4. Freewheel units (clutches) and Rotor Brake
- 5. Lubrication systems
- 6. Housing

¹¹ Peter Lynwander, <u>Gear Drive Systems Design and Application</u> (New York: Marcel Dekker, 1983), iii.

Each of these components can be designed into toolboxes, represented by an icon, that will analyze forces, size the component, and select the correct configuration. For the demonstration of this methodology in the planetary and split torque gearboxes, only gearing, shafting, and gearbox cooling are included. The designer has the freedom to integrate toolboxes as needed. The above list is the suggested minimum for a complete preliminary design.

For the included toolboxes, gear capacity is derived from American Gear Manufacturer's Association (AGMA) standards and includes gear type selection in a variety of external and internal arrangements, evaluation of axial and radial loading, sizing for bending and compressive stress (pitting), and reduced scoring hazard. Shafting withstands simultaneous axial tension stress, vibratory bending stress, and torsional shear stress while ensuring appropriate operation away from critical speeds. Lubrication absorbs gearbox-generated heat through a series of independent splash and force feed oil systems.

The overall system configuration is defined in the government furnished JHL baseline. Figure 7 shows the drive system layout as derived from the furnished 3-view drawings. Included are suggested toolboxes for a complete preliminary design.

WEIGHT ESTIMATION

Three different weight estimation methods are calculated for iterations in the planetary and split torque gearbox model. The solid rotor volume by Willis assumes gear weight is proportional to the solid rotor volume (Fd²) and uses the surface durability factor K for computation.¹² The next two methods are weight equations taken from a NASA sponsored comparative study of Soviet vs. Western helicopters (1983).¹³ The weight equations are from Boeing-Vertol and Research Technology Laboratories (RTL) as cited in the NASA study. The comparative study's Soviet set of equations were from Tishchenko's Soviet Weight Formulae; however, his estimation had to be excluded because the formulae as shown were for tandem helicopters only.

<u>Solid Rotor Volume Method</u>

R.J. Willis's solid rotor volume weight estimation method provides a simple way to estimate gearbox weight and select the optimal reduction ratio in multiple stage drives. The method assumes the weight of a gear drive is "proportional to the solid rotor volume

¹² R.J. Willis, "New Equations and Chart Pick Off Lightest-weight Gears," <u>Product Engineering</u> v. 34, n.s. 2 (January 21, 1963): 64.

¹³ W.Z. Stepniewski and R.A. Shinn, <u>NASA TR 82-A-10 A Comparative Study of Soviet vs. Western</u> <u>Helicopters: Part 2-Evaluation of Weight, Maintainability and Design Aspects of Major Components</u> (Ames Research Center: AVRADCOM Research and Technology Laboratories, 1983).

(Fd²) of the individual gears in the drive"¹⁴ and that a surface durability factor, K, of each mesh is constant. The method is explained in Willis's "Lightest-weight Gears" published in *Product Engineering* in 1963.¹⁵ Similar methods are outlined in Dudley's <u>Handbook</u> of Practical Gear Design (1994) and in AGMA 911-A94, *Information Sheet-Design Guidelines for Aerospace Gearing* (1994).

Simple Gear Mesh

The solid rotor volume maybe expressed as:

$$Fd_{P}^{2} = \frac{126,000HP}{Kn_{P}} \left(\frac{m_{G}+1}{m_{G}}\right) = \frac{2T}{K} \left(\frac{m_{G}+1}{m_{G}}\right)$$

Equation 5

where

F is pinion face d_P is pinion diameter HP is horsepower K is surface durability factor n_P is the pinion speed m_G is reduction ratio T is torque

The solid rotor volume of the gear is proportional to the gear ratio squared:

$$Fd_G^2 = Fd_P^2 m_G^2$$

Equation 6

¹⁴ R.J. Willis, "New Equations and Chart Pick Off Lightest-weight Gears," <u>Product Engineering</u> v. 34, n.s. 2 (January 21, 1963): 64.

¹⁵ R.J. Willis, "New Equations and Chart Pick Off Lightest-weight Gears," <u>Product Engineering</u> v. 34, n.s. 2 (January 21, 1963): 64-75.

The total weight of a gearbox is a function of the sum of solid rotor volume of each gear. For a simple pinion-gear mesh:

$$\sum Fd^2 = Fd_P^2 + Fd_G^2$$

Equation 7

Combining Equation 5, Equation 6, and Equation 7 yields:

$$\sum Fd^2 = \frac{2T}{K} \left(\frac{m_G + 1}{m_G} \right) + \frac{2T}{K} \left(\frac{m_G + 1}{m_G} \right) m_G^2$$

Equation 8

For ease of notation, let: C = 2T / K. Equation 8 can reduce to:

$$\sum \frac{Fd^2}{C} = 1 + \frac{1}{m_G} + m_G + m_G^2$$

Values for the surface durability factor, K, are listed in Table 4.

According to Willis, estimating actual weight is possible by multiplying the total gearbox solid rotor volume by an application factor, c, where c is 0.25 to 0.30 for aircraft application.¹⁶ This weight factor assumes magnesium or aluminum casings, limited life design, high stress levels, and rigid weight controls—all properties that are included in the drive system design of the JHL.

$$W_{gearbox} = c \sum F d^2$$

Equation 9

One of the advantages of the solid rotor method is that the estimated weight includes the entire gearbox with housing, bearings, oil, and gear shafting; thus, the weight of an entire drive system maybe quickly calculated by the sum of the gearbox weights

¹⁶ R.J. Willis, "New Equations and Chart Pick Off Lightest-weight Gears," <u>Product Engineering</u> v. 34, n.s. 2 (January 21, 1963): 70.

and the total shafting weight (as calculated in section SHAFTING on page 86). The accuracy of the weight estimation is a product of the accuracies of the K factor and the application weight factor, c.

Composite Gear Systems

In addition to the weight estimation, Willis details a means to determine the optimal stage reduction ratio that provides the lightest overall weight for the gear system. Most of the stage reduction ratio optimization employs a series of graphs that is not conducive to computer modeling.

Epicyclic or planetary systems may also be optimized with the solid rotor volume method. For a planetary gearset, let:

$$m_s = \frac{d_p}{d_s} = \frac{M_o}{2} - 1$$

Equation 10

where

 m_s is ratio between planet and sun gear M_o is overall ratio P is planet gear subscript S is sun gear subscript R is ring gear subscript

If b represents the number of planets (or branches) in the gearset, then the sun gear volume is:

$$Fd_{s}^{2} = \frac{2T}{bK} \left(\frac{m_{G1} + 1}{m_{G1}} \right)$$

Equation 11

From Equation 10, one can deduce:

$$bFd_P^2 = bFd_s^2 m_s^2$$

Equation 12

The relationship between the ring gear and the sun gear is:

$$Fd_r^2 = Fd_s^2 \left(\frac{d_r}{d_s}\right)^2 0.4$$

Equation 13

where

0.4 is an adjustment to account for weight of the cage structure and housing

The total weight of the planetary gear system is sum of the sun gear weight,

number of planets times the gear weight, and the ring gear weight.

$$\sum Fd^2 = Fd_s^2 + bFd_P^2 + Fd_r^2$$

Equation 14

Substituting Equation 12 and Equation 13 into Equation 14 yields:

$$\sum Fd^{2} = Fd_{s}^{2} + Fd_{s}^{2}m_{s}^{2} + Fd_{s}^{2}\left(\frac{d_{r}}{d_{s}}\right)^{2} 0.4$$

Equation 15

After simplification, the following expression is reached:

$$\sum \frac{Fd^2}{C} = \frac{1}{b} + \frac{1}{bm_s} + m_s + m_s^2 + \frac{0.4(M_o - 1)^2}{b} + \frac{0.4(M_o - 1)^2}{bm_s}$$

Gear Fundamentals

This section includes a brief outline of fundamental gear geometry and properties that will be referenced throughout the remainder of the thesis. For further information, consult any machine design textbook such as Shigley and Mischke's <u>Mechanical</u> <u>Engineering Design</u>. ¹⁹ Another excellent source is the <u>Handbook of Practical Gear</u> <u>Design</u> by Dudley.²⁰ Figure 8 from Shigley and Mischke shows basic gear layout for the simplest of gearing types, the spur gear.

The *reduction ratio* or gear ratio, m_G, of a pair of gears is describes the ratio of pitch diameters of the larger gear to the smaller pinion.

$$m_G = \frac{N_2}{N_1} = \frac{d_2}{d_1} = \frac{n_1}{n_2}$$

Equation 23

where

 m_G is the reduction ratio N is the number of teeth d is the pitch diameter n is the rotational speed

The typical reduction ratio is from 1:1 to 10:1 for most gearing. Modern face gear designs can reach even higher ratios. As gears mesh, the larger gear has a slower rotational speed, n, than the smaller gear. This speed ratio is the same as the gear or reduction ratio and is also expressed in Equation 23.

Even though different size gears rotate at different speeds, the peripheral speed, or *pitch line velocity* (PLV), of a meshing gear pair is the same:

$$PLV = \frac{\pi dn}{12}$$

Equation 24

The *diametral pitch*, P, measures the size of the teeth with respect to the size of the gear and has units of teeth per inch.

$$P = \frac{N}{d}$$

Equation 25

The *circular pitch*, p, is the arc distance from one tooth width and space to the next tooth and has units of inches per tooth.

$$p = \frac{\pi d}{N} = \frac{\pi}{P}$$

Equation 26

The most common tooth shape is the *involute profile*. The involute profile creates a conjugate action similar to cams in order to maintain a steady torque over the meshing gear pair despite the fact that the load on an individual tooth constantly changes magnitude and direction. As involute teeth mesh, the point of contact between them changes. The line in which resultant forces act along is called the *line of action*, L_{cd}, and is shown as line cd in Figure 9. The *pressure angle*, φ , is the angle formed between the line of action and the tangency of the pitch circles. This tooth action is also showed in Figure 9.

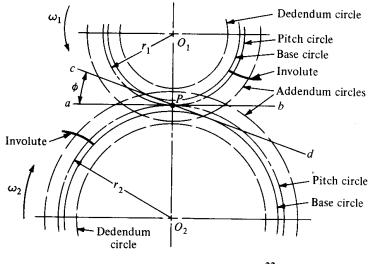

Figure 9: Tooth Action²²

The *contact ratio*, m_c, is the average number of tooth pair in contact during mesh. A higher contact ratio provides better load sharing, smoother meshing, and reduced noise.

Gear Failure Modes

Aerospace gearing is sized on three considerations: bending fatigue, surface compression (Hertz stress), and scuffing (scoring) resistance. A design must include adequate ability to resist all three types of failures. Of the three failures modes, tooth bending has "the most severe consequences . . . whereas pitting and scoring are durability type failures."²³

²² Figure extracted from Joseph Shigley and Charles Mischke, <u>Mechanical Engineering Design</u>, 5th ed (New York: McGraw-Hill, 1989), 533. ²³ American Gear manufacturers Association, *AGMA 911-A94, Information Sheet-Design Guidelines*

for Aerospace Gearing (Alexandria: AGMA, 1994), 41.

Bending stress is concentrated tensile stress at the base of the tooth on the loaded side. A gear tooth can be thought of as a short cantilever beam with a force pushing at the end of the beam. The highest point of stress concentration will occur at the base of the beam, or for gears, at the root fillet (see Figure 10). The ability of a particular gear to resist this stress is called *allowable bending strength* and "is a function of the hardness and residual stress near the surface of the root fillet and at the core."²⁴ To determine failure, allowable bending stress is derated by factors such as dynamic loading, overloading, and reliability. This number is then compared to the bending stress.

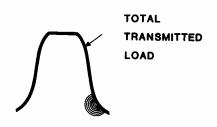

Figure 10: Bending Stress²⁵

Compressive or contact stress causes pitting that weakens the gear surface by increasing local stress concentrations. Gear teeth undergo compression and tension as the tooth rolls through the mesh with the mating tooth.²⁶ Over the life of a gear, this repetitive cycle progressively pits the surface until it eventually leads to a fatigue failure. Figure 11 shows the compressive stress point on a tooth. *Allowable Compressive*

²⁴ American Gear manufacturers Association, *AGMA 911-A94, Information Sheet-Design Guidelines* for Aerospace Gearing (Alexandria: AGMA, 1994), 6.

strength measures the tooth surface's resistance to pitting. To increase compressive strength, aerospace gears are usually strengthened through carburized, case hardening. To determine failure, allowable compressive strength is derated by factors such as surface condition, hardness, and dynamic factors. This value is then compared to the contact stress.

COMPRESSIVE STRESS

Figure 11: Compressive Stress²⁷

As transmitted power increases, the bending stress increases linearly while compressive strength increase as the square root of transmitted power (Figure 12). For the same gear geometry and design, compressive stress will be the higher stress in regions of lower transmitted power while bending stress often dominates the higher power regions.

²⁷ Figure extracted from Peter Lynwander, <u>Gear Drive Systems Design and Application</u> (New York: Marcel Dekker, 1983), 103.

Gear Tooth Stress vs Power Stress (kpsi) Power (hp) -Bending Stress - Compressive Stress

Figure 12: Gear Tooth Stress vs. Power

The Preliminary Design Handbook recommends that a well balanced design occurs where the bending stress to allowable compress stress ratio and the compressive stress to allowable compressive stress are relatively equal and at the desired factor of safety.

Scuffing (scoring) failure occurs when the mating gear welds the metal surface of the mated gear. Although scoring is not a fatigue failure, excessive compressive stress over a period of time will create radial scratch lines in the surface that promotes the onset of scoring.²⁸ Scuffing is a durability failure that may occur instantaneously.²⁹ Heavily loaded, high-speed gears such as aircraft gears tend to fail by scoring.³⁰ The probability of a gear pair to resist scoring is called *scuffing resistance*.

Gear Types and Functions

In a drive system, gears serve to reduce or increase speed, change the direction of drive, and split or combine torque paths. A designer has several different types of gears to select from in order to best achieve the intended function. Spur, helical, and planetary gears transmit torque along a parallel axis. Bevel, worm, and face gears transmit torque along intersecting axis. Crossed helicals or hypoids are used for nonparallel axis gears. For helicopter transmissions, the nonparallel axis gears are not normally used because their efficiency "decreases rapidly as the helix angle increases."³¹ A low inefficiency also applies to worm gears. Table 5 outlines the gear types, functions, and typical uses in helicopter transmissions.

Gear Type	Axis Type	Function	Typical Use
Spur	Parallel	Speed reducer Combine/split paths	Planetary gearing Accessory gearing Tail rotor gearbox
Helical	Parallel	Speed reducer Combine/split paths	Low noise gearing High speed, high load
Bevel	Intersecting	Speed reducer Direction change Combine/split path	Change drive direction Intermediate gearboxes Crown/collector gear

Spur Gears in Helicopter Transmissions

The simplest and "most commonly used" gear in helicopter transmissions is the spur gear.³² The spur gear has straight teeth and transmits torque between parallel axis (Figure 8). Spur gears tend to have lower contact ratios than other types of gears and, therefore, generate more noise. The advantage of spur gears is that they do not develop axial loads or thrust like helical or bevel gears. This eliminates the need for thrust bearings and permits a lighter gearbox weight. Although not traditionally a high-speed gear, aerospace spur gears can operate at high pitch velocities up to 20,000 feet per minute³³ but do generate significant noise. The lack of an axial load makes spur gears well suited for planetary configurations and where permitted.

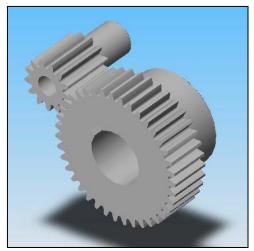

Figure 13: Example Spur Gear

 ³² Headquarters, U.S. Army Material Command, <u>AMC Pamphlet 706-201 Engineering Design</u> <u>Handbook: Helicopter Engineering (Part One: Preliminary Design)</u> (Alexandria: GPO, 1974), 7-5.

Helical Gears in Helicopter Transmissions

Helical gears have teeth angled or twisted to the axis of rotation. This helix angle, ψ , varies from 15 to 30 degrees and generates radial and axial loads on associated bearings. Spur gears are a special form of helical gear with a 0° helix angle.

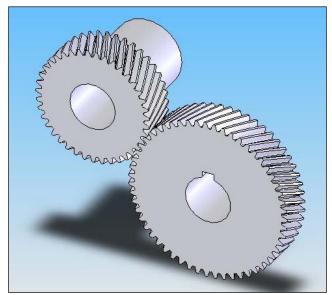

Figure 14: Example Helical Gear

Relative to a spur gear, the effective face width and line of contact in a helical mesh is longer due to the angled nature of the tooth face as shown in Figure 15. This generates higher contact ratios than spur gears and improves load sharing. This improved load sharing permits smoother meshing, reduces noise, and better handles higher speeds and horsepower.

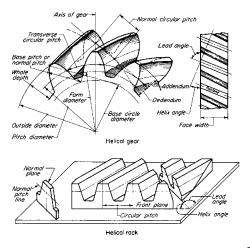

Figure 15: Helical Gear Terminology³⁴

Despite the higher load capacity, the Helicopter Engineering Preliminary Design

Handbook cautions against the employment of helical gears in helicopter transmissions:

"For the same face width, helical gears have more load carrying capacity than spur gears of equal size, are quieter, and have approximately the same efficiency. The overall design is not necessarily lighter; however, because the effect of thrust upon the mounting bearings must be considered. In general, helical gears designed for helicopters use do not offer a tremendous advantage over spur gears of the same size."³⁵

Bevel Gears in Helicopter Transmissions

Bevel gears are the primary means to change direction between intersecting axis.

The shaft angle created between the intersecting axis is typically between 0° and 115°,

with 90° being the most common angle. Straight bevel gears have radial teeth while

spiral bevel gears have curved teeth. Figure 16 shows the bevel gear terminology.

³⁴ Figure extracted from Darle Dudley, <u>Handbook of Practical Gear Design</u> (Lancaster: Technomic, 1994), 1.31.

Straight bevel gears are limited to pitch line velocity less than 1,000 fpm while spiral bevel gears operate beyond 30,000 fpm.³⁶ Due to the restrictive pitch line velocity, straight bevel gears are generally not feasible for primary power paths in helicopter drive systems. Compared to straight bevel gears, spiral bevel gears form a contact area that permits smaller gear pitch for the same contact stress. This allows the use of coarser gears (lower diametral pitch) to increase bending strength.³⁷ The three dimensional curve of spiral bevel gears creates three-dimensional loads requiring multiple bearing restraints. Other forms of bevel gears such as Zerol are possible, but the high speed, high power applications found in helicopter drives best suit spiral bevel gears.

Face Gears in Helicopter Transmissions

Face gears have the teeth cut on top of gear instead of at the outer edge. The face gear tooth changes shape radially. The outside end of the gear limits the outer edge thickness and the pointed tooth limits the inner thickness. They are most similar to straight bevel gears but mate with a standard spur pinion. Gear and pinion have intersecting axis that normally creates a 90° shaft angle. Figure 18 shows the basic geometry for a face gear. Figure 19 shows a face gear-spur pinion mesh.

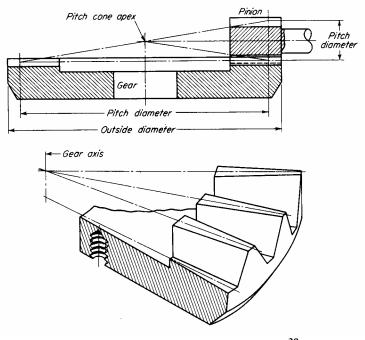

Figure 18: Face Gear Terminology³⁹

³⁹ Figure extracted from Darle Dudley, <u>Handbook of Practical Gear Design</u> (Lancaster: Technomic, 1994), 1.40.

Figure 19: Example Face Gear⁴⁰

In 2004, the Rotorcraft Drive System for the 21st Century (RDS-21) demonstrated that a 5,100 hp face gear, split torque gearbox potentially increases horsepower to weight ratio by 35%, reduces noise by 12 dB, and reduces cost by 20%.⁴¹ Unfortunately, no standardized formulas to rate face gear stresses exist. All current face gear design accomplished with the partial use of Finite Element Analysis (FEA).⁴² The level of design involved with FEA is beyond the scope of this thesis and; therefore, face gears cannot be considered for this model's split-torque transmission. Dudley (1994) does suggest a possible means to preliminary estimate of face gear size. According to Dudley:⁴³

> "Face gears may be handled somewhat similarly to straight bevel gearsets. Generally it will be necessary to use less face width for the face gear than would be allowed as a maximum for the same ratio of bevel gears."

In the future, as face gear analyses improves and the gearing community accepts standards, face gears will likely be the gear of the choice for high reduction ratio transmissions found in heavy lift helicopters.

Rating Spur and Helical Gears

In preliminary design, prior to Finite Element Analysis, the rating methods used by most helicopter gear design engineers are from the American Gear Manufacturers Association (AGMA) standards.⁴⁴ Spur gears are a special case of helical gears where the helix angle, ψ , is zero. As such, the bending strength, compressive strength, and scuffing hazard calculations for both spur and helical gears are found using helical gear calculations. Equating ψ to zero reduces the helical equations to the set of spur equations.

The following force analysis, bending strength analysis, compressive strength analysis, and scuffing risk judgment are derived from Standard ANSI/AGMA 2001-C95 *Fundamental Rating Factor and Calculation Methods for Involute Spur and Helical Gear Teeth*. Additionally, much helicopter specific information and recommendations originates from AGMA 911-A94 *Information Sheet-Design Guidelines for Aerospace Gearing*.

Spur Gear Force Analysis

In general, the stresses on the gear tooth are a function of the transmitted tooth load. In its simplest form, the transmitted load is:

$$W_t = \frac{T}{r} = \frac{2T}{d}$$

Equation 27

where

 W_t is the transmitted load on a tooth T is torque r is the pitch radius or d is the pitch diameter

The total force or load between the driving tooth and the driven tooth is not tangent to the contact point, but is instead along the line of action as measured by the pressure angle. The resultant, total load is typically broken into tangential and radial components as shown in Figure 20.

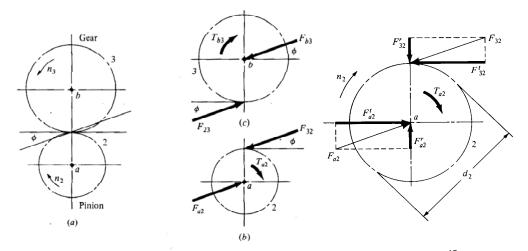

Figure 20: Free Body Diagram of a Simple Gear Train⁴⁵

⁴⁵ Figure extracted from Joseph Shigley and Charles Mischke, <u>Mechanical Engineering Design</u>, 5th ed (New York: McGraw-Hill, 1989), 557.

In Figure 20, the total, resultant load on the larger gear is F_{23} while the load on the smaller pinion is F_{32} . The tangential component of F_{32} is F_{32}^{t} and the radial component is F_{32}^{r} . The reaction forces transferred to the gear are F_{a2}^{t} and F_{a2}^{r} . These reaction forces must be supported by bearings connected to the gearbox housing.

The tangential load serves to transfer the torque between the mating gears. The radial load "serves no useful purpose"⁴⁶ and must be reacted to by supporting bearings to hold the gear in mesh. The tangential and radial components of the total force, W, are:

 $W_r = W \sin \phi$ $W_t = W \cos \phi$

Equation 28

where

W is total force *W_r* is the radial force *W_t* is the tangential force or transmitted load φ is the pressure angle

The relationships between the transmitted load, torque, speed, and power are

shown in Equation 29 and Equation 30:

$$HP = \frac{W_t PLV}{(550)(60)} = \frac{2\pi nT}{(550)(60)(12)}$$

Equation 29

where

HP is power (hp) *PLV* is pitch line velocity (fpm) *T* is torque (in lb) W_t is transmitted load (lb) *n* is rotational speed (rpm) *d* is pitch diameter (in)

Helical Gear Force Analysis

The axial and component forces mentioned by the Preliminary Design Handbook

are drawn in Figure 21 and calculated with:

$$W_r = W \sin \phi_n$$
$$W_t = W \cos \phi_n \cos \psi$$
$$W_a = W \cos \phi_n \sin \psi$$

Contact Stress

The fundamental formula for compressive or contact stress is:

$$s_c = C_p \sqrt{W_t K_o K_v K_s \frac{K_m}{dF}} \frac{C_f}{I}$$

Equation 32

where

 s_c is contact stress (lb/in²) C_p is elastic coefficient (lb/in²)^{0.5} W_t is transmitted tangential load (lb) K_o is overload factor K_v is dynamic factor K_s is size factor K_m is load distribution factor C_f is surface condition factor for pitting resistance F is net face width (in) I is geometry factor for pitting resistance

d is operating pitch diameter of pinion (in)

⁴⁷ Figure extracted from Joseph Shigley and Charles Mischke, <u>Mechanical Engineering Design</u>, 5th ed (New York: McGraw-Hill, 1989), 562.

For a complete detailing of each factor, refer to ANSI/AGMA 2001-C95. A sample calculation of a planetary spur gear is shown in Table 30. A brief outline of the contact stress equation is listed below as it pertains to helicopter gears.

Elastic Coefficient, C_p

The elastic coefficient is a function of the material's Poisson's ratio and modulus of elasticity. Values for steel are approximately $2300 (lb/in^2)^{0.5}$. The elastic coefficient is:

$$C_{p} = \sqrt{\frac{1}{\pi \left[\left(\frac{1 - \mu_{p}^{2}}{E_{p}} \right) + \left(\frac{1 - \mu_{G}^{2}}{E_{G}} \right) \right]}}$$

Equation 33

where

 μ_P and μ_G is Poisson's ratio for pinion and gear, respectively E_P and E_G is Modulus of Elasticity for pinion and gear

Overload Factor, K_o

The overload factor accounts for externally applied loads beyond the tangential load. According to AGMA, "overload factors can only be established after considerable field experience."⁴⁸ In place of field experience, a preliminary value maybe located from Table 6. Considering turbines as uniform prime mover and the changing torque values of the rotors as light shock derives an overload factor of 1.25.

 Table 6: Overload Factor Values⁴⁹

Dynamic Factor, K_v

The dynamic factor accounts for vibration of gear masses and resulting dynamic forces. K_v maybe approximated from Figure 22. Aerospace gears are usually precision ground gears with a high degree of accuracy. High accuracy gears are equivalent to AGMA Q_v 12 to 13.⁵⁰ A value of $Q_v = 12$ promotes successful operation at high pitch line velocities to and beyond 10,000 fpm. From Figure 22, this yields a value from 1.00 to 1.10.

Size Factor, K_s

A size factor of unity is taken for properly heat-treated material.

Load Distribution Factor, K_m

The load distribution factor captures the impact of non-uniform load along the lines of contact. Several conditions influence the load distribution factor to include unmodified or properly modified leads, straddle mounted or overhung pinions, and adjusted gearing at assembly or improved compatibility by lapping. Values range from

1.10 to 1.20 for this design. Calculations for the load distribution factor may be found in Table 30.

Surface Condition Factor, C_f

The surface condition factor is unity for properly ground gears.

Geometry Factor, I

The geometry factor, I, measures the radii of curvature of contacting tooth profiles in order to evaluate the Hertzian contact stress in the tooth. The equation for the geometry factor is:

$$I = \begin{cases} \frac{\cos \phi_t \sin \phi_t}{2m_n} & \frac{m_G}{m_G + 1} \\ \frac{\cos \phi_t \sin \phi_t}{2m_n} & \frac{m_G}{m_G - 1} \end{cases}$$
 external gears

Equation 34

where

 φ_t is the transverse pressure angle m_N is load sharing ratio (1 for spur gears) m_G is the gear ratio

Allowable Contact Stress

The allowable contact stress adjusted for stress cycles, temperature effects, and

reliability must be greater than the calculated contact stress. The relationship between

contact stress and the allowable contact stress is:

$$s_c \le \frac{s_{ac}}{S_H} \frac{Z_N}{K_T} \frac{C_H}{K_R}$$

where

 s_{ac} is allowable contact stress (lb/in2) Z_N is stress cycle factor C_H is hardness ratio factor S_H is safety factor K_T is temperature factor K_R is reliability factor

Stress Cycle Factor, Z_N

Allowable contact stress for a given material is rated to 10^7 load cycles yet most aerospace gears often must last 10^9 cycles. The stress cycle factor adjusts the material contact stress for the required increased in fatigue life. The number of required cycles is:

$$N_{cvcles} = 60Lnq$$

Equation 35

where

 N_{cyc} is the number of stress cycles L is required life (hours) n is speed (rpm) q is number of contacts per revolution

A typical gear pair only experiences one contact per revolution; however, if a gear mates with q other gears it will experience q contacts per revolution. This often occurs in accessory drives and especially in planetary gearboxes. The stress cycle factor for pitting resistance can be found in Figure 23. For cycles beyond 10^7 , Z_N was assumed to be the mean of the shaded value.

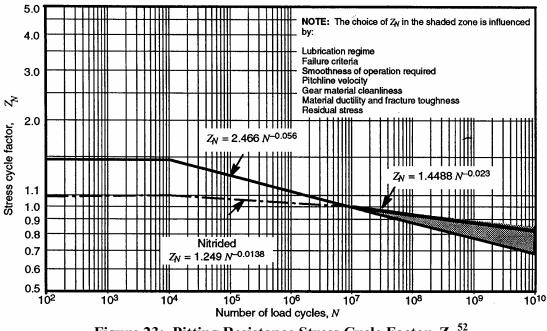

Figure 23: Pitting Resistance Stress Cycle Factor, Z_N⁵²

Hardness Ratio Factor, C_H

Gear capacity increases when the pinion is substantially harder than the gear.

This factor applies to the gear not the pinion.

$$C_H = 1.0 + A(m_G - 1.0)$$

Equation 36

where

$$4 = 0.00898 \left[\frac{H_{BP}}{H_{BG}} \right] - 0.00829$$

 H_{BP} is pinion Brinell hardness number H_{BG} is gear Brinell hardness number For $H_{BP}/H_{BG} < 1.2$, A = 0 For $H_{BP}/H_{BG} > 1.7$, A = 0.00698

⁵² Extracted with permission from AGMA Standard 2001-C95, *Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth*. With the permission of the publisher, American Gear Manufacturers Association, 1500 King Street, Suite 201, Alexandria, Virginia 22314., p. 37.

Safety Factor S_H

The safety factor is added to include uncertainties in design analysis, material characteristics and manufacturing tolerances as well as human and economic risk. For the purposes of preliminary design, measuring these factors is beyond the scope of study and a value of unity is used.

Temperature Factor, K_T

For gear blank temperatures below 250°F, the temperature factor is unity. For gear blank temperatures above 250°F, values above 1.0 should be used. To maintain gear strength, sufficient lubrication is included to ensure temperatures do not exceed the 250°F and a value of unity maybe used.

Reliability Factor, K_R

The reliability factor relates the statistic variations in material to a normal probability distribution. For this normal distribution, the reliability constant is:

$$R_{el} = 1 - nv$$

Equation 37

where

 R_{el} is the reliability constant

n is the number of standard deviations

v is the coefficient of variation (standard deviation/mean), v = 0.1 for spur and helical gears

"For highly reliable aerospace design, a reliability of 3 standard deviations has been used in the past (or 3σ)."⁵³ Three standard deviations (n = 3) yields a reliability of 0.99875 and a constant of $R_{el} = 0.7$. AGMA reliabilities on material properties are listed at a failure of 1 in 100 for a standard deviation of n = 2.326, and a $R_{99} = 0.7674$. The reliability factor is:

$$K_R = \frac{R_{99}}{R_{desired}}$$

Equation 38

where

 R_{99} is the reliability constant for 99% (0.7674) $R_{desired}$ is the reliability constant

For a 3σ aerospace design, K_R is 1.096. The spur-helical model shown in Table 30 of APPENDIX B: SPUR-HELICAL GEAR RATING CALCULATIONS permits user input for other reliabilities from 1 in 10 failures up to 1 in 10,000 failures. This is calculated through a numerical approximation of:

$$R_{el} = \int_{-\infty}^{n} \frac{e^{-\frac{n^2}{2}}}{\sqrt{2\pi}} dn$$

Equation 39

Bending Stress

The fundamental formula for bending stress is:

$$s_t = W_t K_o K_v K_s \frac{P_d}{F} \frac{K_m K_B}{J}$$

Equation 40

where

s_t is bending stress number (lb/in²) *K_B* is rim thickness factor *J* is geometry factor for bending strength *P_d* is transverse diametral pitch (in⁻¹) *P_d* is P_{nd} for spur gears $P_d = \frac{\pi}{p_x \tan \psi_s} = P_{nd} \cos \psi_s \text{ for helical gears}$ *P_{nd}* is normal diametral pitch (in⁻¹) *p_x* is axial pitch (in) *ψ_s* is helix angle at standard pitch diameter

For a complete detailing of each factor, refer to ANSI/AGMA 2001-C95. A complete detailed calculation of a planetary spur gear is in Table 30. A brief outline of the bending stress equation is listed below as it pertains to helicopter gears. Values for W_t , K_o , K_v , K_s , F, and K_m are the same as those for the contact stress formula Equation 32.

Rim Thickness Factor, K_B

The rim thickness factor is a stress concentration factor when the rim thickness cannot fully support the tooth root. All gears in this analysis are designed to ensure sufficient tooth support ($K_B = 1$).

Geometry Factor, J

The bending strength geometry factor accounts for stress concentration from tooth bending and compression from the radial load. For calculations of spur gear geometry factor consult AGMA 911-A94, *Information Sheet-Design Guidelines for Aerospace Gearing*. The guideline includes the geometry factor for both internal and external gears. This method finds the geometry factor, J, by calculating the value at discrete intervals along the edge, A, of the tooth. The point of lowest J value occurs where the bending stress is at its maximum. Associated calculations are in Table 34 and Table 35 of APPENDIX B: SPUR-HELICAL GEAR RATING CALCULATIONS. This is graphically shown in Figure 24.

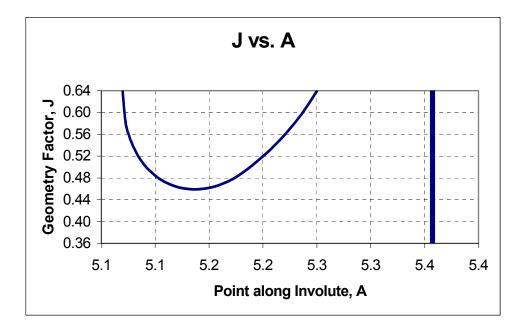

Figure 24: Minimum J Along the Involute Profile

For helical gears, the solution becomes lengthy and is beyond the level of detail required for a preliminary design. Typically, J for helical gears is found in a series of tables. To automate this table look up, the geometry factor for helical gears is estimated by means of least squares regression from the I and J Factor Tables found in AGMA Standard 908-B89, INFORMATION SHEET, *Geometry Factors for Determining the Pitting Resistance and Bending Strength of Spur, Helical, and Herringbone Gear Teeth*.⁵⁴ The estimated J factor lies within ± 5 percent of actual values. Figure 25 and Figure 26 are replicas of graphs shown in Shigley and Mischke (1989) and show graphically J for a standard pressure angle of 20°.

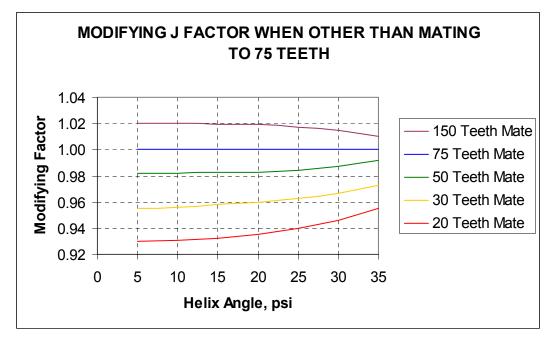

Figure 26: Modifying Factor for J for Different Mating Gears

Allowable Bending Stress

The allowable bending stress (adjusted for stress cycles, temperature effects, and reliability) must be greater than the calculated bending stress. The correlation between bending stress to allowable bending stress is:

$$S_t \le \frac{S_{at}Y_N}{S_F K_T K_R}$$

Equation 41

where

 s_{at} is allowable bending stress (lb/in²) Y_N is stress cycle factor S_F is safety factor

The values for K_T and K_R are the same as those used in section Allowable Contact Stress. Safety factor, S_F , is evaluated in the same method as S_H .

Stress Cycle Factor, Y_N

The stress cycle factor for bending strength is found similarly as the stress cycle factor for pitting resistance. Cycles are calculated from Equation 35 in section Allowable Contact Stress. Figure 27 applies to the bending stress cycle factor.

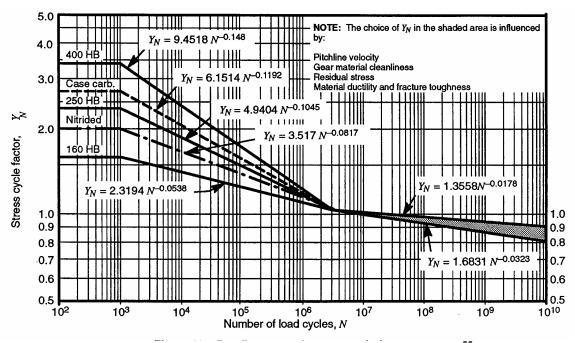

Figure 27: Bending Strength Stress Cycle Factor, Y_N⁵⁵

Spur and Helical Gear Materials

High performance aerospace gears require high tensile strength to endure high bending stresses and high surface hardness to resist pitting from high contact stresses.

⁵⁵ Extracted with permission from AGMA Standard 2001-C95, *Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth*. With the permission of the publisher, American Gear Manufacturers Association, 1500 King Street, Suite 201, Alexandria, Virginia 22314., p. 37.

The majority of helicopter gearing are produced from "heat treated alloy steels and surface hardened."⁵⁶ Aerospace gears are carburized and case hardened to increase the surface hardness. For alloy steel processing, gas carbon is infused into the steel at high temperature, cooled slowly, and repeated at specified levels and temperatures. The carburizing and hardening cycles "produce a very hard, martensitic layer on the surface with a less hard, tough core."⁵⁷ Five different high strength steels are listed in Table 7. Typical applications and relevant material properties are included.

The bending fatigue strength and compressive strength of case hardened steels (AISI 9310, VASCO X2M, PYROWEAR 53, CBS600) are generally the same; however VASCO X2M and PYROWEAR 53 also have high temperature capability to resist scuffing. This makes these two carburized steels the best choice for the scuffing critical main gearbox. In addition to VASCO X2M's high strength, high hardness, high temperature capability, it is also the lightest of the steels. Due to these advantages, the power gears were evaluated using VASCO-X2M. The spur-helical model shown in Table 33 of APPENDIX B: SPUR-HELICAL GEAR RATING CALCULATIONS includes user options to select any of the six listed steels. In accordance with the Preliminary Design Handbook for Helicopter Engineering, "primary gear drives should be made from electrode vacuum melt (CEVM) processed steel.⁵⁸

Scuffing Hazard

Scuffing (scoring) failure occurs when the mating gear welds and tears the metal surface of the mated gear. Scuffing risk is a function of oil viscosity, operating bulk temperature of gear blanks, sliding velocity, surface roughness, gear materials, and surface pressure.⁵⁹ Following Blok's contact temperature theory as outlined by AGMA, scuffing will occur when the maximum contact temperature (t_{cmax}) exceeds a critical

The flash temperature is the local rise in temperature at a specified contact point along a tooth's line of action. The full set of

calculations for the flash temperature is shown in Table 31: Spur-Helical Gear Scuffing. The fundamental formula for flash temperature is:

Helicopters mostly use synthetic oils to provide protection in a wider temperature range (approximately –50 to 400° F) than mineral oils. For MIL lubricants, the scuffing temperature is taken as a constant value with a normal distribution. Table 8 shows the MIL lubricants mean and standard deviation. The Boeing HLH aircraft had great success using MIL-L-23699 with VASCO X2M steel gears. For the lowest scuffing risk, the main gearbox shall use VASCO X2M with MIL-L-23699.

Rating Bevel Gears

Bevel gears stresses and allowables closely follow the procedure for spur and helical gears (section Rating Spur and Helical Gears, p. 49). The AGMA standard for bevel rating is ANSI/AGMA 2003-B97, *Rating the Pitting Resistance and Bending Strength of Generated Straight Bevel, Zerol Bevel, and Spiral Bevel Gear Teeth* and ANSI/AGMA 2005-C96, *Design Manual for Bevel Gears*. All formulas in the section are based upon AGMA 2003-B97. Bevel gear sample calculations are enclosed in Table 36 through Table 42 of APPENDIX C: BEVEL GEAR RATING CALCULATIONS.

Bevel Gear Force Analysis

A bevel gear creates a resultant force that has three components: tangential, radial, and axial loading as shown in Figure 30.

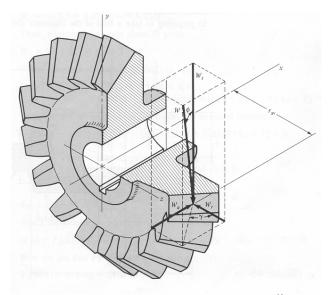

Figure 30: Bevel Gear Tooth Forces⁶⁹

The direction of the radial and axial forces depends upon the type of load face: concave or convex. Load face is a function of the hand of spiral, rotation of gear, and whether the gear drives or is driven. Table 10 lists the combinations for load face.

The axial or thrust load is different for a concave and convex load face. A positive sign indicates a load away from the pitch apex. A negative sign indicates a load towards the pitch apex.

Like the axial force, the radial force is different for each load face. A positive sign (separating force) indicates the direction of force is away from the mate. A negative sign (attracting force) indicates the direction of force is towards the mate.

BEVEL GEAR RATING CALCULATIONS.

Contact Stress

The rating formula for bevel gear bending stress is:

$$s_c = C_p \sqrt{\frac{2T_p}{Fd^2 I} K_o K_v K_m C_s C_{xc}}$$

Equation 49

where

 s_c is calculated contact stress C_p is elastic coefficient C_s is size factor T_P is operating pinion torque (lb in) K_o is overload factor K_v is dynamic factor F is net face width d is pinion outer pitch diameter K_m is load distribution factor C_{xc} is crowning factor I is pitting resistance

Much of the rating calculations for bevel gears follow the rating procedure for spur or helical gears (see page 73). C_p is derived from Equation 33. K_o is from Table 6. K_v is from Figure 22. The factors C_s , K_m , C_{xc} , and I as they apply to aerospace gears are listed below.

Size Factor, Cs

The size factor for pitting resistance accounts for nonuniformity of material and is a function of face width:

$$C_s = 0.125F + 0.4375$$

where

 $0.5 \le F \le 4.5$ for F > 4.5, C_s = 1.0

Load Distribution Factor, K_m

The load distribution factor accounts for non-uniform loads across along the line

of contact. The factor is expressed in Equation 51. $K_{mb}\xspace$ is:

1.00 for both members straddle mounted1.10 for one member straddle mounted1.25 for neither member straddle mounted.

$$K_m = K_{mb} + 0.0036F^2$$

Equation 51

where

 K_{mb} is load distribution modifier F is net face width

Crowning Factor, C_{xc}

The crowning factor compensates for variation in the crowning during

manufacturing. Cxc is 1.50 for properly crowned teeth and 2.0 for larger non-crowned

teeth. A value of 1.50 has been used in the bevel gear calculations.

Geometry Factor, I

The geometry factor for pitting resistance is:

$$I = \frac{s\rho_o \cos\psi \cos\phi}{FdC_i m_{NI}} \frac{P_d}{P_m}$$

Geometry factor calculations for the bevel gear model are included in Table 42: Bevel Gear Pitting Resistance Geometry Factor of APPENDIX C: BEVEL GEAR RATING CALCULATIONS. The geometry factor, I, is found by assuming a critical loading point over the tooth line. The true critical point and I occur as the minimum from Figure 31.

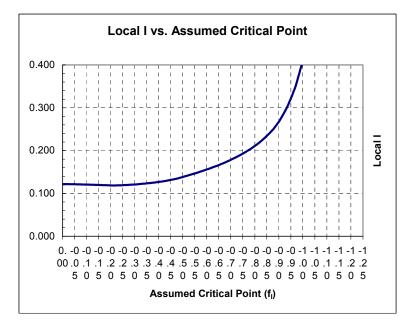

Figure 31: Finding the Bevel Gear Geometry Factor, I

Allowable Contact Stress

The relationship between contact stress and allowable contact stress is expressed in Equation 53. C_L is found from Figure 23. S_H has the same considerations as for spur and helical gears. Unity is used for S_H during preliminary analysis.

$$s_c \le \frac{s_{ac} C_L C_H}{S_H K_T C_R}$$

where

 s_{ac} is allowable contact stress C_L is stress cycle factor S_H is contact safety factor C_H is hardness ratio K_T is temperature factor C_R is reliability factor

Temperature Factor, K_T

For gear blank temperatures at or below 250° F, K_T is 1.0. For operations above

250° F, K_T is:

$$K_T = \frac{460 + T_T}{710}$$

Equation 54

where

T_T is the peak operating gear blank temperature

Reliability Factors, C_R

The reliability factor is approximated in the same way as spur and helical gears but v is 0.156.⁷¹ For bevel gears, Table 11 shows the factor for different requirements. An aerospace value of 1.09 has been applied to the bevel gear model. For this table, C_R is the square root of K_R.

Bending Stress

The formula for bending stress in a bevel gear is:

$$s_t = \frac{2T_P}{Fd} \frac{P_d K_o K_v}{1} \frac{K_s K_m}{K_v J}$$

Equation 55

where

 s_t is calculated bending stress K_o is overload factor K_v is dynamic factor P_d is outer transverse diametral pitch K_s is size factor K_m is load distribution factor K_x is tooth lengthwise curvature factor J is bending strength factor

 K_o is found as in spur and helical gears using Table 6. K_v is from Figure 22. K_m

is the same value as in pitting resistance (Equation 51).

Size Factor, Ks

Instead of being a function of face width like pitting resistance, the size factor for bending stress is a function of outer transverse pitch. For $16 \ge P_d \ge 0.5$, the range of aerospace gearing, the size factor is:

$$K_s = 0.4867 + \frac{0.2133}{P_d}$$

Equation 56

Lengthwise Curvature Factor, K_x

The lengthwise curvature factor is a function of spiral angle and tooth curvature. Table 38 and Table 39 of APPENDIX C: BEVEL GEAR RATING CALCULATIONS contain the relevant geometry and calculations for the factor.

Bending Strength Geometry Factor, J

Calculations for the bending strength geometry factor for bevel gears is complex and beyond the needs of a preliminary design. Often charts are used for faster reference of J in preliminary design. To permit automated estimations, the geometry factor charts are calculated from least squares regressions for the following values:

Straight bevel gears for	$\psi = 0^{\circ}, \phi = 20 - 25^{\circ}, \Sigma = 90^{\circ}$
Spiral bevel gears for	$\psi = 35^{\circ}, \phi = 20^{\circ}, \Sigma = 60 - 90^{\circ}$
	$\psi = 15 - 35^{\circ}, \phi = 20^{\circ}, \Sigma = 90^{\circ}$

Allowable Bending Stress

The relationship between bending stress and allowable bending stress is expressed in Equation 57. K_L is found with Figure 27. K_T estimated with Equation 54. The bevel gear calculations employ an aerospace reliability of 0.99875 (3 σ) which yields a K_R value of 1.20 (Table 11). The bending safety factor has the same considerations as spur and helical gears and is assumed to be unity for preliminary design.

$$s_t \le \frac{s_{ac} K_L}{S_F K_T K_R}$$

where

 s_{at} is allowable bending stress S_F is bending safety factor K_L is stress cycle factor K_T is temperature factor K_R is reliability factor

Bevel Gear Materials

Helicopter gearing demands the high strength, hardened steels that carburized, case hardened alloy steels provide (refer to Spur and Helical Gear Materials on page 66); however, for most helicopter drives, bevel gears are not used at the last few stages of the drive as the thrust loading becomes excessive. Operating earlier in the drive train, bevel gears tend to have higher speeds (rpm) and lower torque values. Steels listed in Table 12 are suggested steels for bevel gears with tested strengths and properties.⁷² All steels are recommended for accessory drives but only Grade 3, carburized and case hardened steels are strong enough for heavy lift main drive applications.

Scuffing Hazard

Bevel gear scuffing hazard is not easily calculated and usually found through testing. The bevel gear rating model, due to these reasons, omits scuffing hazard assessment for bevel gears.

SHAFTING

Simplified Shafting Model

Transmission shafting experiences three-dimensional loads in the x, y, and zdirections; undergoing a combination of bending loads, torsional loads, and axial tension or compression loads. The Preliminary Design Handbook for Helicopter Engineering suggest that even though "a complete analysis normally would not be performed during the preliminary design phase, the principal static and dynamic loads should be analyzed sufficiently to insure structural integrity with the selected size, weight, and performance of the drive."⁷³ Capturing gear shaft loading, to include aerodynamic loads, can quickly become one of the "most complex loading conditions of the drive system."⁷⁴ To estimate the loads and moments on shafts in the preliminary design phase, a simplified loading model for the y and z-directions is created (the x-direction contains the axial loads and does not impact shear or bending moments). Figure 32 shows a loading diagram in the ydirection.

The sample of the shafting tool shown in APPENDIX C: SHAFT DESIGN

CALCULATIONS contains a simple bearing-gear (or loading)-bearing arrangement similar to Figure 33. The example shown in the figure has no moment about the z-axis and a significant moment (-275,000 in lb) moment about the y-axis. Other configurations are possible: the example shown in Figure 32 contains a bearing-gear-gear-bearing arrangement (BGGB). Within the shafting model, the user may select any of the following arrangements:

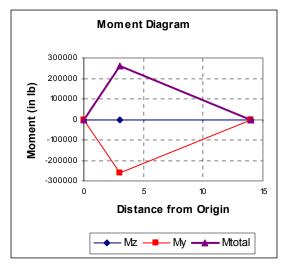

Figure 33: Sample Shaft Moment Diagram

Margin of Safety

Total moment on the shaft does not have a steady direction with respect to the shaft because the shaft is rotating. This loading is "of a vibratory nature" ⁷⁶ and requires an interaction equation to account for vibratory bending stress, axial tension stress, and torsion shear stress. The Preliminary Design Handbook for Helicopter Engineering suggest a margin of safety based upon the maximum shear theory of failure:⁷⁷

$$MS = \frac{1}{\sqrt{\left(\frac{f_b}{F_{en}} + \frac{f_a}{F_{ty}}\right)^2 + 4\left(\frac{f_s}{F_{sy}}\right)^2}}$$

Equation 58

The maximum shear theory accounts for the fact that shaft failures normally occur from fatigue loading.⁷⁸ To save weight, transmission shafting is usually hollow with as high of a diameter to thickness ratio as possible.⁷⁹ The shafting tool in APPENDIX C: SHAFT DESIGN CALCULATIONS iterates the Margin of Safety by varying the shafts

diameter and thickness. The output recommends the lightest shaft that meets the user specified minimum Margin of Safety.

Vibratory Bending Stress

From the maximum shear theory, the alternating bending stress is:

$$f_b = \frac{Mc}{I}$$

Equation 59⁸⁰

where

M is the total bending moment c is the radius where stress is calculated I is the moment of inertia for a hollow shaft $I = \frac{\pi (D^4 - d^4)}{64}$

The maximum bending stress will occur at the outer diameter where product of

the moment and a stress concentration factor, K_b, are greatest:

$$f_{b\max} = \frac{32K_b M_{\max} D}{\pi \left(D^4 - d^4\right)}$$

Equation 60

⁸⁰ Peter Lynwander, <u>Gear Drive Systems Design and Application</u> (New York: Marcel Dekker, 1983), 137.

According to Mischke, the endurance limit or fatigue limit of steels maybe approximated as:

$$F_{en} = \begin{cases} 0.504S_{ut} & S_{ut} < 200 \text{ kpsi} \\\\ 100 \text{ kpsi} & S_{ut} > 200 \text{ kpsi} \end{cases}$$

Equation 61⁸¹

where

 S_{ut} is the ultimate tensile strength

Axial Tension Stress

On helicopter shafting, axial tension or compression stress is the axial loading from helical or bevel gears and also from aerodynamic loads (thrust) on the main rotor or tail rotor drive shafts. Axial stress is the force to area ratio and is expressed as:

$$f_a = \frac{F}{A} = \frac{4F}{\pi (D^2 - d^2)}$$

Equation 62

where

 f_a is axial stress A is cross sectional area F is the axial load D is the outer shaft diameter d is the inner shaft diameter (d = 0 for a solid shaft; D – d = thickness)

⁸¹ Joseph Shigley and Charles Mischke, <u>Mechanical Engineering Design</u>, 5th ed (New York: McGraw-Hill, 1989), 278.

The tensile yield stress, F_{ty} , is also referred to as the yield strength and is an easily referenced material property.

Torsional shear stress

Engine drive and tail rotor drive shafting primarily carry torsional loads.⁸² For the simple model, the torsional shear stress is assumed steady and equal to:

$$f_s = \frac{Tr}{J}$$

Equation 63⁸³

where

fs is torsional shear stress T is torque r is radial distance of the desired stress point J is the polar moment of inertia $J = \frac{\pi (D^4 - d^4)}{32}$

The maximum shear stress will occur along the outside diameter at the greatest

value of the product of the stress concentration factor K_s, and the local moment:

$$f_{s\max} = \frac{16TK_sD}{\pi \left(D^4 - d^4\right)}$$

Equation 64

 ⁸² Headquarters, U.S. Army Material Command, <u>AMC Pamphlet 706-201 Engineering Design</u> <u>Handbook: Helicopter Engineering (Part One: Preliminary Design)</u> (Alexandria: GPO, 1974), 7-3.
 ⁸³ Peter Lynwander, <u>Gear Drive Systems Design and Application</u> (New York: Marcel Dekker, 1983), 138.

Most often, the critical area on a shaft occurs at a sharp narrowing of the shaft diameter. This increased stress is captured with a stress concentration factor, K_s.

For the maximum-shear stress theory, the endurance limit stress is one-half the yield strength:⁸⁴

$$F_{sy} = 0.5F_{ty}$$

Equation 65

Critical Speeds

One of the greatest challenges to shaft design is the divergence phenomenon nicked named "critical speeds." As shaft speed increase, residual unbalances create large centrifugal forces. The centrifugal forces bend the rotating shaft and are balanced by the elastic forces in the shaft. This balance is likened to a skipped rope.⁸⁵ As the shaft increases past this critical speed, the bent mass moves to the centerline until the shaft rotates about its axis.

Operation below the critical speed is called a subcritical condition while operation above the critical speed is termed supercritical. For safe operation, subcritical shafts must not operate within 30% of the critical speed. Supercritical shafts must not operate within 10% of the critical speed.⁸⁶ Drive shafts connecting gearboxes and engines

usually operate below or between critical speeds.⁸⁷ If a shaft is designed to run above the critical speed, damping is required during run-up as the shaft passes through the avoid range.

Nonuniform Shafts

Nonuniform shafts are defined as having a nonuniform rigidity or concentrated masses such as splined gears. A variation on Rayleigh's method as outlined in the Preliminary Design Handbook for Helicopter Engineering derives the natural frequency by comparing kinetic energy with potential energy.⁸⁸ This is done by dividing the shaft into concentrated mass of m_i connected by massless, stiff shaft elements (Figure 34). The shaft deflection from a bending moment maybe calculated by numerically integrating:

$$y = \int \int \frac{M}{EI} dx dx$$

With the deflection known, the kinetic energy is:

$$T = \frac{\omega^2}{2} \sum_{i=1}^p \frac{w_i}{g} y_i^2$$

Equation 67

where

T is kinetic energy (in lb) ω is shaft frequency w_i are lumped weights g is 386.4 in/sec² y_i is element deflection

The potential energy is:

$$V = \frac{1}{2} \sum_{i=1}^{p} w_i y_i$$

Equation 68

where

V is potential energy (in lb) w_i are lumped weights y_i is element deflection

The natural frequency is found by equating potential energy to kinetic energy.

Expressing the natural frequency as a critical speed in rpm yields:

$$N_{c} = \frac{60}{2\pi} \sqrt{g} \sqrt{\frac{\sum_{i=1}^{p} w_{i} y_{i}}{\sum_{i=1}^{p} w_{i} y_{i}^{2}}}}$$

Equation 69

where

N_c is critical speed (rpm)

Uniform Shafts

For shafts with uniform mass distribution and with no moment restraint on the bearings, there will be no bending moment. This is common in the tail rotor drive shaft connecting the main transmission to the tail rotor gearbox. This type of shaft maybe modeled as a beam with length L where bearings support the ends. The critical speed for a uniform shaft is a "function of the mean radius of the tube and the length between supports."⁹⁰ The critical speed, N_c , is expressed in rpm as:

$$N_{c} = \frac{30\pi^{3}}{2\pi L^{2}} \sqrt{\frac{4gE\pi (D^{4} - d^{4})}{64\pi\rho (D^{2} - d^{2})}}$$

<u>Shaft Materials</u>

Lightweight metals such as aluminum alloys and titanium are preferred for shafts in helicopter drives systems. Great strength can be gained from high diameter to thickness ratios that permits the use of weight saving aluminum alloys. The Boeing HLH

employed aluminum alloy for most shafting except in the main rotor drive shaft. There, the stronger titanium was added to withstand high aerodynamic loads. The shafting model has several aluminum alloys, steal 4340 and the same titanium found in the HLH for user selection (Table 49). All designs presented in this thesis use Aluminum Alloy T7075 and Titanium Forging 6 A1-4V. Table 13 has representative samples from the material database.

GEARBOX COOLING

Although gear efficiency is high, at the power levels of the JHL sizeable amounts of heat must be dissipated by the lubrications system. Mesh efficiencies maybe taken as:⁹²

HP:

- 1. 99.5% per spur mesh
- 2. 99.5% per helical mesh
- 3. 99.5% per bevel mesh
- 4. 99.25% per planetary set

Power loss from a gear mesh is a function of the efficiency, η , and applied power,

$HP_{loss} = (1 - \eta)HP$

Equation 72

Assuming any power loss is converted into heat by the meshing gears, the oil

temperature rise across the gearbox is:

$$\Delta T = \frac{Q}{MC_p}$$

M is oil flow (lb/min) Q is heat generated (Btu/min) where Q = HP (42.4) Cp specific heat of oil ≈ 0.5 Btu/lb-°F

For example, in the sample spur gear calculations of Table 32 and summarized below, total oil flow required to maintain a ΔT of 30° F is 5.32 gallons.

Aerospace designs normally operate up to a maximum ΔT of 45° F.⁹³ The calculations used in the lubrication and cooling model utilize a ΔT of 45°F to determine oil flow required. A typical helicopter main gearbox lubrication system is shown in Figure 36.

TRADITIONAL PLANETARY MODEL

The traditional planetary drive system model consists of a 2-stage planetary main gear box where the sun gear of the first stage is the input and the carrier of the second stage is the output and transfers torque to the main rotor shaft. The main gearbox is similar to the Boeing prototype HLH's forward or aft transmissions. The tandem rotor HLH transmission had a 2-stage planetary gearset driving both the forward and aft rotors. A sketch of the HLH's transmission layout is shown in Figure 37 and the 2-stage planetary aft transmission is shown in Figure 38.

<u>Drive Arrangement</u>

The Supplemental Information defines the JHL baseline aircraft with 3 scaleable turbine engines, a single main rotor and traditional anti-torque tail rotor (Figure 4 and Figure 5). While the Boeing HLH was a tandem helicopter, the aft and front 2-stage planetary main gearbox was used as the model for the JHL planetary gearbox. Figure 39 shows the planetary drive system that fits within the requirements of the JHL Supplement.⁹⁷ Although there are many possible configurations that satisfy the JHL Supplement's requirements, this arrangement follows a traditional layout for helicopters.

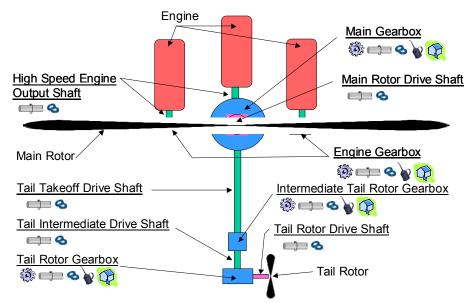

Figure 39: Drive System Components

⁹⁷ Aviation Applied Technology Directorate, "Joint Heavy Lift Supplemental Package" (Fort Eustis: AATD, November 4, 2004).

Engine Input Gearbox

Each turbine engine undergoes an initial reduction ratio at the Engine Input Gearbox. Inside the gearbox is a freewheeling unit to allow autorotation. The left and right Engine Input Gearbox have a pair of bevel gears to change the direction of the drive 90°. The bevel gear also mates with an accessory bevel gear to power the left or right accessory set. The center engine has a helical idler and helical gear to power the accessory set.

Bevel Crown

The bevel crown resides below the 2-stage planetary set and receives the power input from the Engine Gearbox Output Shaft. Three bevel pinions drive the Crown Bevel gear which drives the 1st stage sun gear.

Oil Cooler Gearbox

A tail takeoff bevel pinion mates with the crown gear and links an oil cooler located directly aft of the main gearbox. The oil cooler gearbox distributes power to the main oil cooler, an auxiliary accessory module, and the tail take off shaft.

Intermediate Tail Rotor Gearbox

The tail takeoff shaft has 12 equally spaced 45" segments linked down the tail boom of the aircraft. A bevel gear set conducts a 60° direction change to power the intermediate tail rotor shaft. The shaft connects to the tail rotor gearbox at the top of the vertical tail.

Tail Rotor Gearbox

The Tail Rotor Gearbox conducts a final speed reduction and a 90° direction change to drive the Tail Rotor Drive Shaft.

Planetary Main Gearbox

The planetary gearbox overall ratio is considered an independent variable; however, the individual reduction ratio of each planetary stage is minimized for weight according to Willis' "Lightest-weight gears" procedure for compound drives.⁹⁸ Figure 40 shows the weight minimization for a 2-stage planetary gearset.

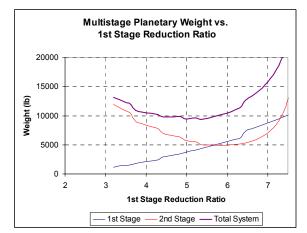

Figure 40: Example Optimized 2-Stage Planetary Gearbox

⁹⁸ R.J. Willis, "New Equations and Chart Pick Off Lightest-weight Gears," <u>Product Engineering</u> v. 34, n.s. 2 (January 21, 1963): 65.

For a given overall reduction ratio, the procedure assumes a first stage gear ratio. The corresponding second stage ratio is the quotient of the overall ratio to the 1st stage ratio.

$m_{G2} = M_G/m_{G1}$

Equation 74

The total rotor volume is computed for each assumed first stage reduction ratio. The procedure iterates until the minimum total rotor volume (and weight) is found. The iteration is complicated by the fact that the number of planets is a function of a planetary gear's reduction ratio. As the stage reduction ratio increase, the number of allowable whole planets decreases. This function is not continuous but a step since it is impossible to have a fraction of a planet installed. The discrete function is what gives rise to the step-like nature of the curves. These calculations are found in Table 54: Planetary Drive Minimum Weight Solution.

<u>Planetary Drive Modeling</u>

To capture the behavior of the planetary drive, the weight estimation and shafting elements were entered into Model Center 6.0. Model Center's planetary drive model consisted of a weight estimation spreadsheet (Table 50) and individual shaft sizing spreadsheets (refer to SHAFTING for shaft discussion and APPENDIX C: SHAFT DESIGN CALCULATIONS for sample calculations). Shafting spreadsheets were added to include the engine output shaft, main rotor drive shaft, tail takeoff shaft, intermediate

108

tail rotor shaft, and tail rotor drive shaft. Figure 41 shows the planetary drive model in Model Center:

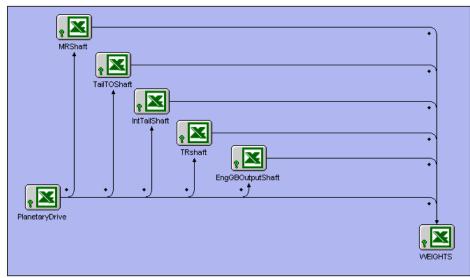

Figure 41: Planetary Drive in Model Center

The weight estimation spreadsheet calculated all speed, torque, power, and power losses for each gear and shaft of the drive system. This spreadsheet also provided a total gearbox weight based on the solid rotor volume method, and total drive system weight estimations based on the Boeing-Vertol and RTL weight equations. Since the solid rotor volume method only estimates gearbox weight, shafting linking gearboxes needed inclusion. To accomplish this, individual spreadsheets were added into Model Center for all external shafts connecting the drive's gearboxes. A final spreadsheet called "WEIGHTS" summed all gearbox, shaft, and drive system weights to allow easy comparison of estimates.

Weight Estimation Results

Weight equations results for the baseline JHL from the solid rotor volume method plus individual shafting calculations, Boeing-Vertol, and RTL yielded a minimum weight results shown in Table 15. The optimal baseline design was determined through a variable metric method optimization in Model Center. The drive system design methodology compares very favorably to the Boeing-Vertol and RTL predictions.

SPLIT TORQUE MODEL

A split-torque drive offers great weight savings potential. Litvin (2000) sums up the benefit of the split torque model best by commenting:

> "Gear volume is proportional to the square of gear diameter, while torque-carrying capacity of gearing is proportional to lower order determinants of gear diameter (depending on whether bending or compressive stress evaluations are being used). Therefore, if torque is reduced by approximately one-half (based on the actual percentage of torque split between gears) for a load carrying gear, the weight of the gear can be reduced by more than one-half, due to the square relationship of weight to gear diameter."⁹⁹

The Mi-26 houses a highly successful, operational split-torque helicopter

transmission that is close to the JHL needs. The 105,000 lb Mi-26 is about 35,000 lb

lighter than the JHL Baseline. The Mi-26 main gearbox served as the initially layout for

the JHL torque-split drive. Below is a picture of the Mi-26 main gearbox.

Drive Arrangement

With a dual engine configuration, the Mi-26 transmission splits the torque evenly three times for a total torque split of 8 (2^3) per engine. The engine input shafts extend through the main gearbox housing power two bevel gears for the main drive and one set of bevel gears to the tail rotor shaft. The total gearbox reduction ratio is 62.52.

The split-torque drive study in this thesis follows the same layout and torque splits as the Mi-26; however, the baseline JHL's overall reduction ratio is 130. This figure is almost twice that of the Mi-26's ratio and presents a new challenge in design. Additionally, the JHL has a third engine which means the combiner receives input from 24 combiner pinions as opposed to the Mi-26's 16 pinions. Finally, the tail rotor must also have a bevel takeoff from each combiner to permit power from all three engines.

Torque Split Drive Modeling

The model employed in Model Center for the torque split drive is similar to the planetary drive model. Shafting spreadsheets capture shaft weight for the main rotor drive shaft, tail shaft, intermediate tail rotor shaft, and tail rotor drive shaft. Speed, torque, and power were calculated for the split torque drive much the same way the planetary drive spreadsheet functioned. All calculations are shown in APPENDIX E: SPLIT TORQUE DRIVE CALCULATIONS.

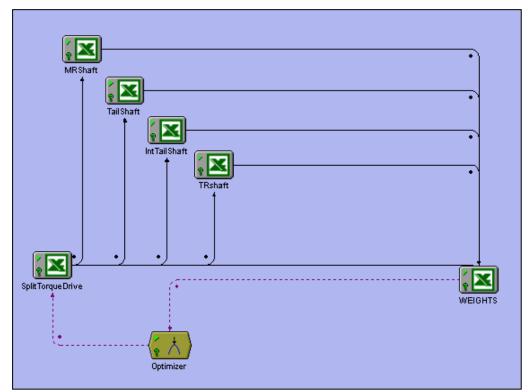

Figure 44: Split Torque in Model Center

Weight Estimation Results

To achieve the higher reduction ratio required by the baseline JHL, slightly higher gear ratios at each stage are required. Especially important is the final stage between the combiner pinion and combiner. In the last stage, the Mi-26 has a reduction ratio of 8.76:1. In the JHL, the last stage has a reduction ratio of 11-13:1. The last stage reduction ratio results in a larger combiner gear, increasing the total size of the main gear box. A reduction ratio close to 12:1 places the main gearbox at the space limits for the

current structure. A reduction ratio just over 13:1 causes the pitchline velocity of the spur combiner to exceed the general spur gear limit of 4,000 feet per minute.¹⁰²

As shown by Figure 45, the success of the split torque drive as configured depends greatly on the final stage reduction ratio.

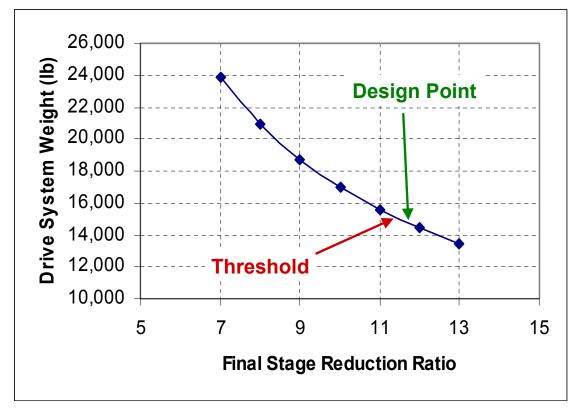

Figure 45: Drive System Weight vs. Final Reduction Ratio

From the graph, the threshold point where the split torque drive becomes lighter than the 15,200 lb planetary drive occurs at a reduction ratio of 11.2:1. The size of the combining gear imposes a limit of 11.7:1 on the reduction ratio. This limit becomes the design point for the final reduction ratio and the main gearbox.

¹⁰² Darle Dudley, <u>Handbook of Practical Gear Design</u> (Lancaster: Technomic, 1994), 1.27.

At 11.7:1, the total system weight is 14,749.6 pounds. Boeing-Vertol and RTL's weight equations are a little higher than the solid rotor volume and shafting estimate. In both the planetary and split torque drive systems, the model's shafting weight is almost double the RTL's estimate.

RESPONSE SURFACE METHODOLOGY

Overview

Response Surface Methodology (RSM) is a technique to build and optimize empirical models. Through multivariate least squares regression, RSM approximates output response to input parameters with a polynomial empirical equation. This multivariate equation is known as the Response Surface Equation (RSE). To intelligently obtain the regression data, a Design of Experiments (DoE) is created. A properly designed DoE with RSM can capture the underlying factors which influence a response. Using a polynomial equation as an RSE permits rapid, efficient prediction of a much more complex, time consuming calculation.

Initially, a Taylor series, second order approximation form is used for the RSE:¹⁰³

$$R = b_0 + \sum_{i=1}^{k} b_i x_i + \sum_{i=1}^{k} b_i x_i^2 + \sum_{i=1}^{k-1} \sum_{j=i+1}^{k} b_{i,j} x_i x_j + \varepsilon$$

Equation 75

where

R is the dependent parameter (response of interest) b_i are regression coefficient for the first order terms b_{ii} are coefficients for the pure quadratic terms b_{ij} are the coefficients for the cross-product terms x_{ij} are the independent variables ϵ is the associated error for neglecting higher order effects

¹⁰³ Michelle R. Kirby, "An Overview of Response Surface Methodology" as presented in AE6373 lecture (Atlanta: Georgia Institute of Technology, August 25, 2004), 7.

Design of Experiments are "a series of tests in which purposeful changes are made to input variables so that one may observe and identify the reasons for change in an output response."¹⁰⁴ The DoE varies input parameters in an intelligent pattern to capture the response of the system over the entire design space.

To model the drive system responses, an initial DoE casts a wide net around many independent variables in order to obtain data that identifies the most influential factors. This is called a screening test. A Pareto Chart is a convenient method to graphically communicate the percent of response variability, in the given ranges, attributed to a single input parameter. Generally, 20% of the input variables are responsible for 80% of the system variability. The purpose of the screening test is to identify the most important factors influencing the response.

Once the most important independent variables are identified, a second DoE is established that contains only those selected important input parameters. This DoE typically has more independent variable levels and iterations to yield higher fidelity to the final model. The regression data is again fit to the second order linear model and the final RSE is calculated.

<u>Planetary Drive RSM</u>

The planetary drive has 12 independent variables for weight estimation. These variables are:

1. Main rotor power

¹⁰⁴ Michelle R. Kirby, "An Overview of Response Surface Methodology" as presented in AE6373 lecture (Atlanta: Georgia Institute of Technology, August 25, 2004), 8.

- 2. Main rotor rpm
- 3. Planetary reduction ratio
- 4. Tail rotor rpm
- 5. Engine input gearbox reduction ratio
- 6. Tail rotor gearbox reduction ratio
- 7. Engine rpm
- 8. Intermediate tail rotor reduction ratio
- 9. Accessory rpm
- 10. Accessory power
- 11. Oil cooler power
- 12. Tail rotor power required

A DoE with a fractional (half) factorial (2,048 runs) on the twelve variables

permitted screening of six variables (for cumulative 95%) as shown by the Pareto chart;

however, tail rotor power required was kept to allow for future regression of shaft weight.

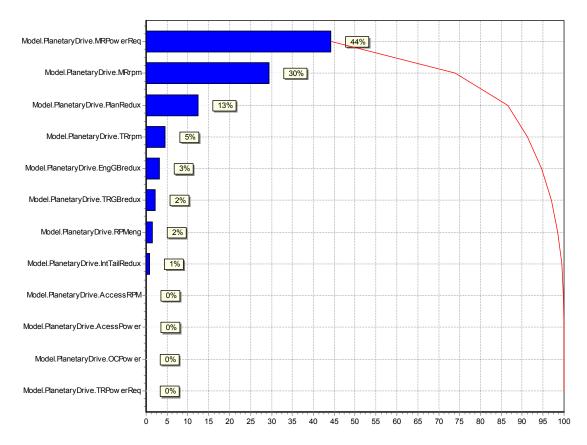

Figure 46: Planetary Drive Screening Test Pareto Chart

For the remaining seven variables, a 3-level full factorial DoE (2,187 runs) captured the data for the RSE model. The RSE formulation from JMP is shown in APPENDIX F: MODEL FIT FOR PLANETARY DRIVE. An optimization within Model Center of the baseline JHL showed the following input variables for the RSE:

 Table 19: Baseline Planetary Drive RSE Input Variables

The fitted RSE for the planetary drive demonstrates excellent promise as a weight estimation model. The optimized baseline drive system weight within Model Center was 15,203 pounds while the RSE predicted 15,262 pounds. This residual of 59 pounds is a -0.4% model percent error, which is only a slight deviation from the weight prediction. The RSE has an R² of 99.9% and an R² Adjusted of 99.9%--both well above the recommend 90%. The Actual by Predicted plot (Figure 47) is excellent with vary little deviation from the perfect fit line. The Residual by Predicted plot (Figure 47) shows a good normal distribution about the mean and no discernable pattern—all good indications. The total span of error (about 600 lbs) over the minimum predicted (about 10,000 lbs) is close to 6%--an acceptable, but not ideal, level for this model fit.

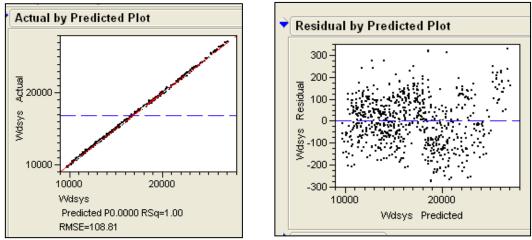

Figure 47: Planetary Drive RSE Model Fit

Split Torque Drive RSM

The split torque drive has lower variety of shafts and gears than the planetary

drive. For the split torque drive nine independent variables were present in the

calculation of weight:

- 1. Combiner reduction ratio
- 2. Main rotor HP
- 3. Main rotor RPM
- 4. Tail rotor HP
- 5. Idler reduction ratio
- 6. Engine RPM
- 7. Tail rotor gearbox reduction ratio
- 8. Tail rotor RPM
- 9. Intermediate tail rotor reduction ratio

The screening test consisted of a 2-level full factorial with 512 runs (2^9) . As shown by the Pareto Chart, the intermediate tail rotor reduction ratio and tail rotor reduction ratio accounted for little influence on the weight response. Of the nine variables, these two were eliminated from consideration.

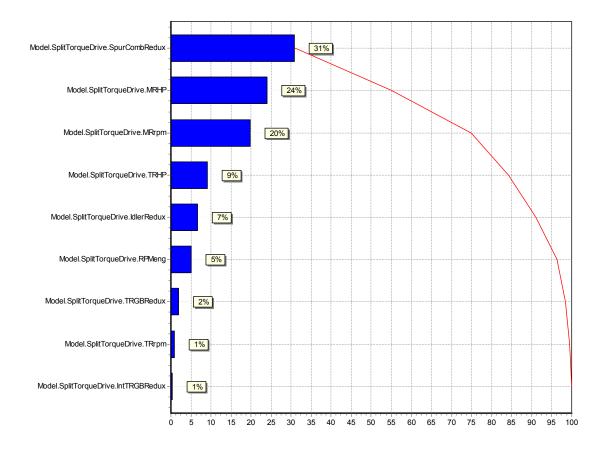

Figure 48: Split Torque Screening Test Pareto Chart

The second DoE consisted of a 3-level, full factorial with 2,187 (3⁷) runs. From this data, a response surface was generated using JMP (see APPENDIX G: MODEL FIT FOR SPLIT TORQUE DRIVE for regression analysis data). Of the 2,187 data sets, 49 or

2.2% did not converge properly for weight estimation and were removed as outliers from the regression data.

The initial model fit for the split torque drive was not as successful as the fit for the planetary drive. Although the initial RSE had an R^2 of 99.6% and an R^2 Adjusted of 99.6%, the Actual by Predicted and Residual by Predicted plots (Figure 49) proved unacceptable. The Actual by Predicted plot showed decent adherence to the perfect fit until about 30,000 lbs; however, the model over predicts at weights above 30,000 lbs. This is confirmed by the Residual by Predicted plot's undesirable S-curve trend. The RSE fit had to be improved for the model to acceptable and serve as a useful tool.

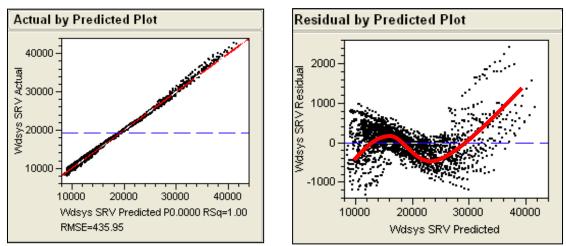

Figure 49: Initial Split Torque RSE Model Fit

To improve the model fit, several techniques were attempted. Results are shown in Table 21. The final model fit output from JMP is listed in APPENDIX G: MODEL FIT FOR SPLIT TORQUE DRIVE.

Table 21. Split Torque Would Fit Comparison

Square Root Transformation RSE	14,384	2.5%							
Cube Root Transformation RSE	14,478	1.8%							

Table 21: Split Torque Model Fit Comparison

The first technique applied was to bias the fit towards the baseline by adding three data points of the baseline input and response to the DoE data table. Although the biasing did improve the baseline residual, the impact was so minor as to not warrant further application. The second technique consisted of checking different transformations on the response. Drive system weight was transformed by 3/2 power (R

= $W_{dsys}^{3/2}$), square root (R = $W_{dsys}^{1/2}$), and cube root (R = $W_{dsys}^{1/3}$) and then fitted against the 2d order polynomial RSE. The 3/2 power transformation exacerbated the model fit's flaws while transforming in the $\frac{1}{2}$ power direction improved the model in the correct direction (Table 21). Extending to a cube root transformation showed even better results and served as the final model fit. Higher root transformation did reduce the baseline residual; however, the reduction is minimal and higher root transformations experience a condition of diminishing improvement.

The final RSE fit for the split torque drive exhibited good potential as a weight estimation model. The optimized baseline drive system weight within Model Center was 14,750 pounds and the RSE predicted 14, 478 pounds. This 272 pound residual is a 1.8% model percent error. The RSE posses an R2 of 99.9% and an R2 Adjusted of 99.9%---both well above the recommended 90%. The Actual by Predicted plot (Figure 50) is acceptable with improved adherence to the perfect fit line at extremes. The Residual by Predicted plot (Figure 50), showed adequate normal distribution and little discernable pattern. The total span of error (about 0.7 lbs^{1/3}) over the minimal predicted (20 lbs^{1/3}) is approximately 3.5%--a good value for this model.

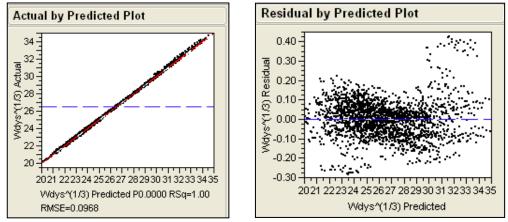

Figure 50: Split Torque Final RSE Model Fit

CONCLUSIONS

A drive system design methodology was presented that permitted integration of detailed component design and allowed higher fidelity and better weight estimates. The methodology is an open architecture allowing the designer to insert and remove component tools as necessary. Component tools for gearing, shafting, and gearbox are included as examples.

A spreadsheet component tool to size spur, helical, or bevel gears for bending and compressive stress as well as scuffing resistance revealed several important conclusions about heavy lift drive gearing. Due to high torque values in the main gearbox, the scuffing hazard proved the most difficult design criteria to meet. VASCO X2M steel with MIL-L-23699 provides the best resistance to scuffing for these high torque gears. Bending strength sized planetary gears due to the reduction in strength from reverse loading. Aerospace gears throughout the drive train operate at very high pitchline velocities requiring high precision, ground gears to reduce dynamic loading and create smooth meshing. Due to the critical nature of helicopter gearing, high reliabilities of a minimum 3σ at a long 2,500 to 5,000 hour life are required. Despite high efficiency gearing, the massive amounts of transmitted power produce a sizeable amount of lost power transformed into heat. In addition to increasing the gear blank temperature and higher scuffing hazards, these high heat quantities require large amounts of force-fed oil flow to properly cool gearing.

129

A shafting model is also included as a component tool and integrated into the solid rotor volume weight estimate model. Due to the vibratory nature of the bending moments, an interaction equation is required to calculate a total margin of safety for the combined bending, shear, and torsional stresses experienced by a rotating shaft. From this interaction equation, it was shown that helicopter drive shafts tend to have high diameter to thickness ratios in order to withstand the high torsional stress while maintaining light weight. Throughout the drive system, hollow aluminum alloy shafts were preferred because of great weight savings; however, for shafts with high applied loads such as the main rotor and tail rotor drive shafts, heavier titanium had better resistance to bending and shear stresses. For uniform shafting, the critical speed is simply a function of shaft radius and length. For nonuniform shafting with mass concentrations or bending moments, the critical speed is calculated using a variation of Rayleigh's method. From the variation, the natural frequency is found by comparing the shaft's kinetic energy to its potential energy. For the heavy lift helicopter, shafts linking gearboxes are uniform and typically operate at subcritical speeds while gear shafts and drive shafts are nonuniform and may operate at supercritical or subcritical speeds.

The methodology demonstrated good potential to serve as a system weight predictor. Methodology weight estimates (combined solid rotor volume method and shaft weight estimations) for both a planetary and split torque drive system were within approximately 10% of the Boeing-Vertol and RTL weight equation estimates (Table 22).

 Table 22: Total Drive System Weight Method Summary

This weight estimation method was successfully applied to a traditional multistage planetary drive and to a split torque drive similar to the Mi-26's main gearbox. For the planetary main gearbox, low planetary reduction ratios are preferred because of increased load sharing gained from more planets. The ideal main gearbox reduction ratio is a function of each stages reduction ratio. The shown split torque drive included three torque splits for a final stage total of eights paths per engine. Splitting the torque showed great weight savings potential over the traditional, 2-stage planetary drive system if high reduction ratios (above 12:1) can be achieved in the final stage. This requirement for a high final reduction ratio face gears.

Approximating the more complicated model created in Model Center by Response Surface Methodology produced good results. The planetary model's initial RSE was an excellent fit with a model percent error less than 1%; however, the split torque regression required a cube root transformation to yield a workable model with a model percent error less than 2%. With correct model fitting, Response Surface Methodology demonstrated the ability to serve as a simplified response predictor for a more complicated, high component integrated drive system model.

FUTURE WORK

The addition of detailed, user friendly tools for bearings, freewheeling units, rotorbrakes, splines, housing, structural support, and aerodynamic loads on drives shafts is needed to fully capture the drive system behavior and find a feasible, optimized solution.

In addition to the RSM, the drive modeling must be examined from a probabilistic point of view. Placing distributions on assumptions and key factors will capture the uncertainty associated with a design. The impact and overall probability of success may then be judged through the application of Monte Carlo simulations.

Lastly, the face gear holds potential to save weight in split-torque designs and are "optimal for large reduction ratio applications" that occur in helicopter drive trains.¹⁰⁵ Testing of prototype face gears for a split-torque helicopter transmission by Handschuh, Lewicki, and Bossler (1992),¹⁰⁶ and the recent success of the 5,100 HP RDS-21 Demonstrator Gearbox (2004),¹⁰⁷ have confirmed the weight saving benefits. Handschuh, Lewicki, and Bossler indicated that face gears can have "an improved weight advantage compared to spiral bevel gears at [reduction] ratios higher than approximately 3.5:1." Face gear technology is a major facet of the RDS-21 and future drive systems.

 ¹⁰⁶ Handschuh, R., D. Lewicki, and R. Bossler, <u>NASA TR 92-C-008 Experimental Testing of Prototype Face Gears for Helicopter Transmissions</u> prepared for "Gearbox Configurations of the 90's" sponsored by the Institute of Mechanical Engineers Solihull, West Midlands, United Kingdom, October 28, 1992.

Development of a standardized, analytical estimate of gear stresses becomes the key to integrating face gear technology into the future drive system design methodology.
